To

MY FRIEND, "THE CHIEF,"
HERBERT CLARK HOOVER

IN TOKEN OF MY
GREAT ADMIRATION AND
AFFECTION FOR ONE WHOSE
NOBILITY OF CHARACTER
AND BRILLIANCY OF INTELLECT
ARE EQUALLY OUTSTANDING,
THIS BOOK IS DEDICATED

PREFACE

THIS book grew out of the author's work as Chief of the Statistical Division of the United States Food Administration from June 11, 1917 to March 1, 1919. When plunged into the business of making war it was found in this country, as it had been in every other of the fighting nations, that many data were lacking which were essential to any reasonable prediction as to what the food position was going to be with the passage of time. The work of the Statistical Division of the Food Administration in its early days was chiefly a desperate struggle to get some sort of approximation to an answer for such questions as: "What is our normal consumption of milk?" "How much wheat can we spare for export?" "How much meat must be conserved to meet export demands and still not injure physiologically the home population?"

As time passed and the organization of the food producing and distributing agencies of the country was perfected, we came to possess unique sources of information from which questions like the above could be answered. Still more broadly it was perceived that we had better material than had ever been available before on which to attempt a thorough and searching statistical survey of the food resources and food consumption of the United States. In the summer of 1918 I began the task of putting together the material. It has proved a far greater labor than was anticipated.

No attempt has been made to discuss the related literature. This omission is deliberate. For the United States certainly a statistical analysis of the sort here attempted is pioneer work. In my opinion what is most wanted, is a careful, critical, clear and unbiased presentation of the statistical data, rather than my opinion as to their interpretation. The data comprised in this book have interest and significance, it is believed, for a wide range of specialists, including certainly the student of agricultural problems, of nutritional physiology, of economics, of sociology, and of commerce. The point of view of the writer has been to act as the hod-carrier to these various specialists, delivering to them a mass of carefully made bricks, believed to be solid and true. From these

bricks they can build whatever structures they like, far better than the statistical hodsman could hope to.

At this point I wish to acknowledge my indebtedness to my loyal assistants in the Statistical Division of the Food Administration, Dr. Frank M. Surface, Mr. Stephen Chase, Mr. Mortimer B. Lane, and Mr. John Rice Miner, without whose aid this work could not have been completed for many months, if not years, and without whose advice on many technical points the results would have been far from having that degree of reliability which I think they now possess. The diagrams are the work of Mr. Rudolph von Huhn, whose untiring efforts to make the most significant graphical representations of the data have enhanced the value of the work to the reader.

Finally, I wish to pay tribute to my Chief in the Food Administration, Mr. Herbert Clark Hoover, whose never-failing interest in the project, whole-hearted encouragement of its prosecution, and penetrating criticism of the results at all stages, contributed much to whatever measure of success may have been attained in the investigation. Such keen and just insight into the problems and methods of scientific research as is an integral part of Mr. Hoover's daily thought and life, is as rare among great administrators as it is welcome.

RAYMOND PEARL.

February, 1920.

THE NATION'S FOOD

CHAPTER I

THE FOOD PROBLEM

The substantial truth of the slogan "Food will win the war" must now be evident to any thinking person. The relatively enormous proportion of the total man power involved in direct or indirect military activities in all of the belligerent nations except the United States, with the heavy involvement of farm man power in this country; the disparity between tonnage supplies and needs which resulted in a far-reaching dislocation of the normal world trade in foodstuffs; the widespread crop reduction below the normal in 1916 and 1917; and other factors served to make the food problem assume a direct military importance in the late conflict, vastly greater than it had ever had before. The western world had come to look upon its food supply as an inexhaustible thing. Free communication, both international and national, had made famine or anything approaching famine a thing unheard of or undreamed of in the part of the world of which we are speaking. Food was to be sure sometimes relatively scarce, but that condition only meant at the worst high prices for a time. All this the war changed. All too many people during the last three years have been brought within a threateningly short distance of the grim specter of famine.

With the ending of actual warfare and the opening of the stage of negotiations on November 11, 1918, the food problem of the world became not less, but even more pressing than it had been during the war. In the first place the moral and spiritual motive on the farmer's part to keep production at a maximum in order to help "win the war" ceased at once to operate. In the second place, as events have shown, the internal political readjustments which are taking place in every country involve a general disorganization which is not conducive to the production of maximum crops. Hunger is a potent stimulus to Bolshevism. But unfortunately Bolshevism is not a good alleviant of hunger. It works in fact quite the other way, except for the very short period in which the uprising

masses steal any goods, edible or other, which the classes may happen to have on hand. In consequence of the destruction of war, on the one hand, and Bolshevism on the other hand, the world food problem is made more difficult by the additional burden of countries normally food exporting, such as Russia, Germany and Austria, and devastated countries like Poland, Northern France, Serbia, etc.

The food conditions in Europe on December 1, 1918, are shown graphically in Fig. 1.

FIG. 1.—Food map of Europe.

This diagram shows clearly what a pressing matter the after-war food problem is.

From the beginning of the war Germany realized the menace of food shortage. Her very position at the outset, with the certainty of an effective blockade sooner or later, made it imperative for her to take stock of her food resources, both actual and potential. Hence in the report of the Eltzbacher Commission we had the first serious attempt at a survey of national food resources. Since that time

all of the other principal belligerent countries have carried through similar studies, with greater or less critical, scientific acumen.

It is the purpose of this present book to give as careful and critical analysis of the food resources of the United States, as it is possible to make with existing information. The need of such a study for the United States at this time is greatly enhanced and indeed made imperative, by reason of the fact that to an ever-increasing degree this country is being called upon to feed Europe. England, France, and Italy bore the brunt of the actual fighting for nearly four years. This splendid stemming of the tidal wave of mingled science and savagery which is Hun warfare, was only accomplished at the expense of every form of productivity other than military. Especially has agricultural production suffered in these three countries because of two factors: first the drawing of agricultural labor into the armies, which could not be prevented, on the one hand because of the fearful necessity for men at the front, and on the other hand because it has not been practically feasible to demonstrate to draft officials the essentially skilled character of agricultural labor. In the second place the enemy occupation of some of the best agricultural land, in the case of France and Italy, has made tremendous inroads on the national production of foodstuffs.

With the existing shortage of ocean tonnage, and the enhanced needs for what does exist, America becomes almost the only practically available source from which may be eked out the diminished food resources of the Allies. The extent to which these countries have relied upon the United States for food since the beginning of the war is not generally recognized. It will be profitable to examine cursorily the facts.

There are here tabulated (Table 1) the total exports to the United Kingdom, France, and Italy of each of the more important food materials from the beginning of the war until our entrance, viz., from July 1, 1914, to April 1, 1917, and for comparison with this the total exports of these same commodities to the same countries for the first year of participation of the United States in the war, April 1, 1917 to April 1, 1918. In subsequent tables these commodities are reduced to nutritive units and the three periods—before the war, since the beginning of the war until our entrance, and our first year as a belligerent, are compared.

The detailed exports for the two periods, since the beginning of the war until our entrance, and our first year in the war, with the

* Net decrease.

period from July 1, 1914 to April 1, 1917 reduced to a yearly average, are shown in Table 1. In right-hand columns are given the increase or decrease in the year's exports of each commodity during our first year as a belligerent. These increases or decreases are shown both in absolute and percentage figures.

It will be noted from the last lines of Table 1, that during our first year in the war, the total exports to the Western Allies were over 600,000,000 pounds, or 280,000 metric tons, *less* than the average for the preceding years of the war. The percentage figures show, however, this was a decrease of only 3.95 per cent. As will be shown in subsequent chapters our available food resources from which to ship abroad were notably low in 1917-18.

The figures for wheat show the one really large decrease which is, of course, due to the small size of the 1917 crop. Wheat exports decreased over 68 million bushels, or 56 per cent. of the average for the first years of the war.¹ It is interesting to note that every other cereal shows an increase, rice leading with an increase of 153 million pounds or 4822 per cent. Wheat flour made a substantial gain of 7 million barrels or 114 per cent. The increases and decreases were made in classes, all the cereals *increased* except wheat, all the fats show quite a marked *decrease*, as do the dried fruits. Canned beef, fresh beef, bacon, and hams and shoulders increased, while pickled beef, fresh pork and pickled pork decreased. Condensed milk increased over 230 million pounds, or 386 per cent. Refined sugar decreased 380 million pounds, or 44 per cent. Linseed oil cake and meal exports, which decreased after the beginning of the war, again show an increase in 1917-18 of about 87 million pounds, or 211 per cent. There were no exports of corn oil from April 1, 1917 to April 1, 1918.

In order to show that, while the total exports of wheat to our Western Allies have decreased, there has been a greater degree of concentration, Table 2 has been prepared, which gives for different periods the total wheat exports to the Western Allies and to all other countries with their percentages of the total exports.

¹ The export figures here used are the official returns of the U. S. Department of Commerce. They do not include shipments to our own Expeditionary Forces abroad, or to certain other destinations. More detailed discussion of this point will be presented in a later chapter. For the present purpose, which is merely to give a general picture of the export situation, these incomplete figures will suffice.

TABLE 2.—EXPORTS OF WHEAT AND WHEAT FLOUR, IN TERMS OF WHEAT (Bushels)

Period	Western Allies*	Other countries	Total all countries	Per cent. total to Western Allies
Yearly average for 3 pre-war years.....	43,322,626	79,390,160	122,716,785	35.3
Yearly average since the beginning of war to April 1, 1917.....	151,186,982	111,740,770	262,927,754	57.5
Our first year in the war, April 1, 1917 to April 1, 1918.....	114,766,614	39,366,380	154,132,998	74.5
Month of April, 1918.....	11,134,633	1,229,309	12,363,942	90.1

* Includes only United Kingdom, France and Italy.

For the last column of Table 2 it may be seen that the percentage of total exports of wheat to the Western Allies has been steadily increasing. During our first year in the war when we exported 154 million bushels the Allies received 114 million bushels or about $\frac{3}{4}$ of the entire exports. In the month of April, 1918 the United Kingdom, France and Italy received over 90 per cent. of all the wheat exported.

Tables 3, 4 and 5 show the total exports expressed in nutritive units, (1) for the average of the three years preceding the war, (2) for the average of the period from the beginning of the war until our entrance, and (3) for our first year in the war.

TABLE 3.—AVERAGE ANNUAL EXPORTS OF FOODSTUFFS TO THE WESTERN ALLIES FOR THE 3 PREWAR YEARS, 1912-14, IN TERMS OF NUTRITIVE UNITS

Country	Protein, lb.	Fat, lb.	Carbohydrates, lb.	Millions of calories	Per cent. of total calories
United Kingdom.....	446,943,599	475,390,782	2,366,080,388	7,238,373	85.8

In Fig. 2 the facts regarding the exports of essential nutrients since the beginning of the war are shown graphically.

It is apparent that average rate of export of protein and of carbohydrates to the Western Allies from the United States increased after we became an active belligerent, by an amount well over 200 per cent. as compared with our prewar exports to these same countries. In the case of fat the increase is not nearly so great, but still notable enough if considered by itself, amounting to over 80 per cent. more than the prewar rate.

These facts make apparent the necessity for taking such an account of stock of our food resources as this book attempts. Great

as this country is in its agricultural power it is not an inexhaustible reservoir. We have to feed something over a hundred million people at home out of our supply. It is obviously the part of wisdom, in the face of lack of knowledge as to how long the excessive demands on America for food may continue, to attempt to arrive at as accurate a balance sheet as possible of what we may count on in the way of food, and what we need for ourselves in order to keep this population in a sufficiently nourished and hence efficient condition. And it must be always remembered that for the next few years at

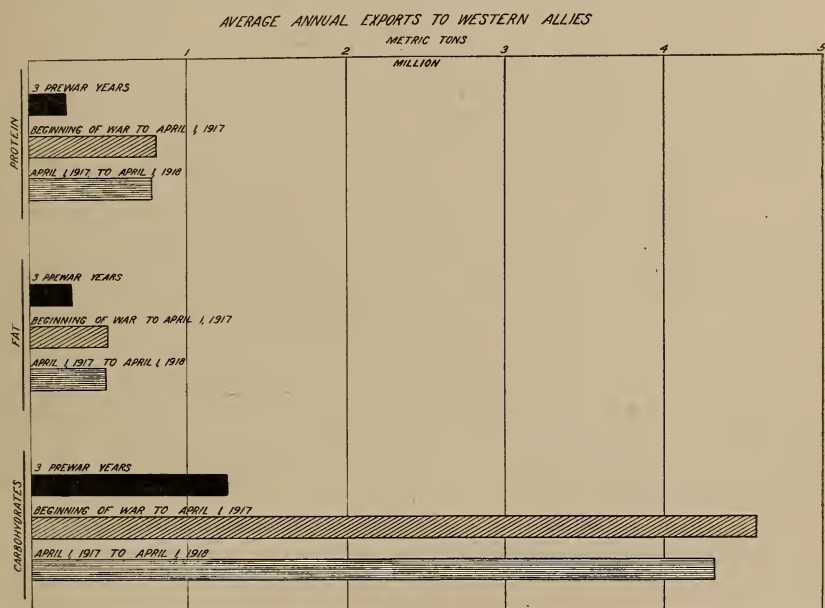

FIG. 2.—Diagram showing exports of essential nutrients to Western Allies, United Kingdom, France and Italy, before and since the beginning of the war.

least now that the war has ended, the demand from Europe on America for food is certain to be extremely heavy, perhaps as heavy as during the period of active fighting. The reconstruction period seems likely to be a long and painful one. Furthermore the neutral countries in Europe, with the cessation of hostilities and the lifting of embargoes, will turn perforce to America for the replenishment of their sadly depleted food resources. Altogether it is apparent that the food problem will be a very real one in the life of this country for several years to come. It is the chief purpose of this volume to contribute in some degree a critical physiological basis for the intelligent discussion of this problem.

CHAPTER II

THE PLAN

The basis of any adequate survey of food resources must be essentially physiological, rather than one of commodities or trade. The value of foods fundamentally depends upon their content of nutrient materials. To get information on how much food a nation produces or needs for consumption, which shall be an adequate guide for the administration of social problems such as those created by war, it is necessary to have something more than raw crop statistics. Modern research in the physiology of nutrition has shown that besides a sufficient gross amount of protein, fat and carbohydrate, it is necessary to have in a diet which is adequately to sustain an individual or a nation a certain amount of accessory substances, certain ones of which are generally called vitamins.¹ These substances are not uniformly or universally distributed among edible materials. Consequently an adequate survey of food resources must take into account not alone the total supplies and consumption of protein, carbohydrate and fat, but also the distribution of these nutrients among the several classes of commodities, the vitamin content of which is known, in general terms at least.

So then, specifically, the problems with which this investigation has to do are such as these:

1. How much protein, fat and carbohydrate is annually produced in the United States in forms used, or usable, as human food?
2. How much of these basic nutrients in forms available for human food are imported and exported each year?
3. What quantities of basic nutrients are annually consumed as human food?
4. What is the distribution of the nutrients produced, imported, exported and consumed, among the several classes of food commodities?

¹ For general résumés of modern work on the physiology of nutrition, see Lusk, G., *The Elements of the Science of Nutrition*, 3d Edit., Philadelphia, 1917; McCollum, E. V., *The Newer Knowledge of Nutrition; the Use of Food for the Preservation of Vitality and Health*, N. Y., 1918.

5. What proportion of the total nutrient material produced in the United States is consumed by domestic animals?

These problems are at once physiological and social. The war situation made it urgently necessary to undertake their solution. Properly to attack these problems demanded the working out and application of novel methods, because the problems themselves are new.

The first step obviously is to make a classification of food materials, so that one may effectively apply proper statistical and physiological methods. Broadly speaking the ultimate sources of food are the soil and the sun. The energy derived from the sun through the mechanism of the green plant builds up the inorganic chemical elements of the soil, air, and water, into compounds which can be utilized as food by man, either directly or secondarily in the form of the products of animals which have been nourished on the primary foods of the plant world.

For the purpose of statistical analysis all nutritive materials produced and consumed fall into one or another of the following categories, which are obviously based on the considerations set forth in the preceding paragraph.

I. Primary Foods

Including all plant materials used as human food or fractions of such materials, and all animals or animal products in which the animal gets its nourishment from some source other than the primary feeds and fodders as defined below, either

- (a) Directly as harvested, with only such sophistication as comes from cooking: such as, for example, potatoes, fish, oysters.
- (b) In derivative form, where by process of manufacture a food product is prepared from a raw plant product: such as, for example, wheat flour or cottonseed oil.

II. Primary Feeds or Fodders

Including all plant materials or fractions of such materials used for the nourishment of domestic animals, either

- (a) Directly as harvested, such as the coarse grains, or
- (b) In derivative or manufactured form, such as manufactured feeds.

III. *Secondary Foods*

Including all edible products of animals used for human food, the animals being nourished with primary feeds and fodders. This rubric comprises animal foods produced,

- (a) Directly, without involving the death of the producing animal, such as, for example, honey, eggs, or milk, and
- (b) Derivatively, involving the death of the animal, such as, for example, the meats.

The basic idea in this classification is, of course, to allocate the nutrient resources of the nation according to the usage made of them. We have certain products of the soil, and of the seas and fresh water lakes and streams, which are directly produced and directly consumed as human food. To produce a crop of potatoes or of cod fish or oysters it is not necessary to feed out to the growing crop some other crop such as hay or grain. Therefore these are direct, primary food products. On the other hand there are many foods such as the meats, eggs, etc., where to obtain a pound of protein, or fat, or carbohydrate for human consumption it is necessary to use a certain amount of other protein, fat, and carbohydrate, primarily produced, as fodder or feed. Human food produced in this manner is obviously secondarily produced and cannot be allowed to count in the net nutritive balance sheet on the same basis as the primarily produced food. It is a relatively more expensive form of nourishment.

It is evident that under this classification many raw food materials will of necessity fall in part into two or more categories. For example, to take the case of wheat, the major part of the raw grain is ground into flour and as such used as human food, but in the process of making the flour there is produced a certain amount of feeding stuffs, bran, middlings, etc., which only indirectly contribute to human nutrition through the products of animals which eat these wheat feeds. Finally a certain small proportion of the wheat grain is fed directly as such to live stock. Similar considerations apply to very many other food materials. That all this adds a considerable complexity to the problem is evident. But it is equally clear that if anything approaching reliability in the final result is to be attained due regard must be paid to these complicated subdivisions in usage of the raw food materials. Otherwise the same nutritive

material will be duplicated in the accounting and a misleading result reached.

The general plan of this study has been first to determine as accurately as possible from existing official statistics, for each year from 1911 to date, the amount of the basic nutrients, protein, fat, and carbohydrate,

- (a) produced,
- (b) imported,
- (c) exported,

classifying the results under the main headings given above. From this tabulation as a base one may then proceed to calculations of consumption and the like.

In making up the basic tables each commodity or derivative of a commodity has been listed separately and converted as such into nutrient values. In the matter of units of measure the following general plan has been followed: in all basic tables the quantities of production, export and import are first given in the American units (bushels, pounds, gallons, etc.) of the original statistics. These quantities are then all converted into metric tons.¹ All nutrient values, protein, fat, and carbohydrate, are given in metric tons. Energy values are expressed in millions of small calories.²

Regarding the sources of the basic statistics the following general statement may be made here, to be supplemented by more detailed statements in subsequent chapters where necessary. For *production* figures the fundamental sources, in the case of primary products, are the successive *Year Books* of the U. S. Department of Agriculture. Each volume of this publication carries as an appendix statistical tables giving the Department's official figures of crop production. A secondary source for crop production figures is found in the successive volumes of the *Monthly Crop Report* of the U. S. Department of Agriculture. Its figures are again official and form the basis of the tabulations of the *Year Book*, but frequently give more detailed information. Reliable statistics of the derivative products such as flour, meals, etc., are much more difficult to obtain than crop production figures, for the reason that they are not officially collected and published. In this field resort has been

¹ The metric ton = 2204.6 lb.

² A small calorie is the amount of heat necessary to raise 1 gram of water 1° Centigrade.

had to a variety of sources, such as trade papers, census returns, special *ad hoc* inquiries of manufacturers, etc. At the appropriate points detailed statements as to how our figures were arrived at will be forthcoming.

Export and import figures are taken from the official reports (annual and monthly) of the foreign commerce of the United States compiled by the Department of Commerce. In a few cases where it has been clear from information available to the Food Administration that the official figures of the Department of Commerce were in error we have not hesitated to use other and, as we believe, more correct statistics, but in each such case specific notation of the fact is made.

In the computation of nutrient values use has been made chiefly of the factors given by Atwater and Bryant.¹ It has been necessary, in some cases, to supplement their tables from data given by Leach² and Henry and Morrison.³

All calculations in this work have been repeatedly checked and every possible precaution taken to guard against error. It is too much to hope that so extensive a piece of statistical work should be without errors, but I hope that their number is small and their net significance in the final results negligible.

CHAPTER III

THE PRIMARY FOOD PRODUCTION OF THE UNITED STATES

(Commodity References Nos. 1-35)

We come now to the direct statistical analysis of food resources under the first rubric, the primary food materials. At the outset it should be understood that the tables in this and subsequent chapters do not include every single commodity used as food. Many minor and insignificant items are omitted, from necessity. There simply are no statistics available for such things as mushrooms, wild berries, game, and a large number of other subsidiary food items. The omissions, however, are really not a matter of concern. The total contribution of these omitted subsidiary items to the total nutritional intake of the population is statistically insignificant. It undoubtedly does not amount in the aggregate to as much as the probable error of the statistics of the staple foods. The endeavor has been made to include in the tables every item of food which fulfilled the following two requirements: (a) a significant contribution to the national nutrition, and (b) available statistics either for an exact determination or a reasonable estimate.

Table 7 gives for each year from 1911 on the *production* of all the primary food materials produced in the United States for which any sort of statistics could be obtained. It is necessary for an understanding of the tables that a precise explanation be given of each item.

Before passing to this detailed discussion certain matters of general explanation should be presented.

1. All years, unless otherwise specified in particular cases, are fiscal years beginning on July 1 of the first year named and ending June 30 of the second named year. This fiscal year is chosen for two reasons, viz.:

(a) It is the period for which all import and export statistics are normally compiled by the U. S. Department of Commerce.

(b) It includes within its limits practically the complete harvesting period of all crops grown in continental United States.

2. In the columns giving nutrients, the terms protein, fat, and carbohydrate are used in the following senses, which are in accord with general usage in works on nutrition:

(a) *Protein*.—An arbitrary term used to designate a group of chemical compounds assumed to include all the nitrogenous matter of the food except the nitrogenous fats. It is quantitatively estimated by multiplying the total nitrogen found by analysis by the factor 6.25.

(b) *Fat*.—Under this term is included the total ether extract. The ether extract includes, besides the true fats, fatty acids, nitrogenous fats (lecithins), and other related compounds.

(c) *Carbohydrates*.—The carbohydrates include sugars, starches, cellulose, gums, woody fibers, etc. Carbohydrates are usually determined by difference in the analysis of foods.

3. In no case is any account taken of "carry-over" in the production figures at this point. There is no necessity for including figures on "carry-over" when, as in the present study, a period of several years in time is included in the statistical analysis. Under such circumstances the inclusion of carry-over or invisible stock estimates would simply complicate and confuse the result. The correct theory of the matter appears to be that in any investigation of food resources and consumption over a period of years, residual stocks should be regarded as having passed into consumption or export or both. This they always do sooner or later. Full physical proof of this fact was found in the United States in the summer of 1918 when the country had no appreciable residual stocks of certain important commodities at the end of the crop year. A further discussion of "carry-over" in the case of certain crops will be given in a later chapter.

4. Unless otherwise specified in particular cases, use has been made throughout of the following general plan of determining nutrient values. First there are made necessary general deductions from the total crop to cover the loss for food usage resulting from any or all of the following general causes:

(a) Seed for next crop.

(b) Loss from failure to harvest, and incomplete harvesting, frost damage, and other factors lowering, *in the field*, the total net production.

(c) Nutritional loss from plant diseases or weather injury which do not affect the total quantity harvested but do affect the

food usage of the product. A good example here is anthracnose in beans, which diverts to lower grade food or fodder uses significant portions of the harvested crop.

(d) Loss from vermin (rats, mice, etc.) and other causes in storage and transportation, including decay and spoilage of perishables.

(e) Manufacturing losses.

(f) Diversion to industrial, non-food uses, including the making of alcoholic beverages.

Having made the best estimates possible of such general deductions Atwater and Bryant's nutritive factors are applied to the residue remaining. Now these authors give, for all foods in which there are losses or wastage in cooking or preparation for the table, two sets of nutritive factors; one for the food "as purchased," the other for the "edible portion." In both cases the analyses are complete (*i.e.*, the percentages add to 100), the percentage of "refuse" being put into the "as purchased" as a part of the analysis. In consequence one gets the same net amount of protein, say, in the apple crop if he applies the Atwater-Bryant "as purchased" percentage 0.3 to the weight of the whole crop, as he will get if he first deducts 25 per cent. from the weight of the crop, which is their figure for inedible refuse, and then to the balance left applies their "edible portion" protein factor of 0.4. Since the net result is the same as we have in all but one case, namely fish, used the "as purchased" factor on the whole crop remaining after the general deductions above explained. In all cases the amounts of protein, fat, and carbohydrate given in the tables in this book are *net* amounts remaining after (a) general deduction for seed, crop spoilage and losses, etc., and (b) after allowance for refuse in preparing food as purchased for eating.

We may now proceed to a detailed discussion of the sources, significance and corrections of the several items in Table 7.

GRAINS AND THEIR DERIVATIVE PRODUCTS

1. **Corn Meal (Maize Meal) and Corn Flour.**—There are no official annual statistics as to the production of corn meal in this country. The only available data are the returns of the Census of Manufactures¹ made at quinquennial intervals. To arrive at

¹ The exact bibliographical reference to the last volume of the summary of this work is "Abstract of the Census of Manufactures, 1914," Washington, 1917. Detailed chapters regarding special commodities are separately issued.

annual estimates the following procedure was adopted. To the census returns as to production of corn meal and corn flour in merchant mills for the four years 1899, 1904, 1909, 1914, a parabola was fitted by the method of least squares. From the fitted line annual figures were read off for the years up to 1917-18. In this last year there has been such a marked and abnormal increase in the corn milling capacity of the country that another procedure was adopted to reach an estimate. For the first six months of the year (July, 1917 to December, 1917, inclusive) the value was estimated from the parabola. For the last six months (January to June, 1918, inclusive) the total rated capacity of existing and operating merchant corn mills was taken, on the assumption that under the present stress of need the mills were operating to full capacity.

The procedure so far gave the production of corn meal in merchant mills only. More than in the case of any other grain, corn is custom ground. The farmer takes his grain to the mill and pays the miller to turn it into meal. The amount of such custom milling of corn is too great to neglect. It has, however, been steadily decreasing, at least since 1899. In that year 30.5 per cent. of the total output of corn meal in the country was ground in custom mills. In 1909 this percentage had dropped to 20.7. We have assumed that it has continued to decrease at the same rate since that time, and have accordingly applied a sliding scale increase to the merchant mill output relative to the custom mill to get the total.

2. Hominy and Grits as Corn.—Again there are no official annual statistics of production, so that recourse was had to the quinquennial returns of the Census of Manufactures. To the figures of output of hominy in merchant mills (in terms of bushels of corn used in the manufacture of this product) for the years 1904, 1909, 1914 a straight line was fitted by the method of least squares, and the values read off for individual years, and by extrapolation after 1914. There appeared to be no sufficient ground for differential treatment of the year 1917-18 in respect of this commodity. Also no correction has been made for manufacture of this product in custom mills. In 1909 only approximately 1 per cent. of the total was so made, and the proportion was decreasing rapidly.

3. Wheat (Nutrients in Flour).—The basis for the computation here was the official statistics as to the wheat crop in successive years as given by the Department of Agriculture. For the years 1911-12 to 1915-16 the crop figures were taken from the U. S.

Department of Agriculture Yearbook¹ for 1916, p. 571. For the year 1916-17 the crop figure was taken from the Monthly Crop Report² (U. S. Department of Agriculture) for December, 1917, p. 117. For the year 1917-18 the Food Administration estimate of the wheat crop, based on its marketing statistics was used.

Starting with the total crop figures the following deductions were made in order to arrive at the net amount available for human consumption: (a) the amount used for seed, determined on the basis of acreage and the average amount per acre used for seeding purposes in the different states; (b) 5 per cent. of the crop to cover wastage in storage and transit, loss by vermin, etc.; (c) 2 per cent. of the crop to allow for the amount fed to live stock direct. This last item, of course, is included later in the computations of fodder and feed, but in the present chapter we are dealing strictly with human food. The proportion of 2 per cent. of the crop so used is the Department of Agriculture's average estimate on the point. (d) The amount used in the manufacture of alcoholic beverages. This is an extremely small item, amounting to an annual per capita consumption of less than 0.006 lb., all of which was stopped during our participation in the war owing to the closing of distilleries.

No deduction is made for industrial non-food or non-fodder uses of wheat for the reason that the amount of such use is so insignificantly small that anything approaching an accurate estimate is utterly impossible. The 5 per cent. general deduction for loss may probably be safely regarded as also including any non-food uses other than those already allowed for.

Having made the above mentioned deductions it is assumed that the balance remaining is ground into flour and feeds. In Table 7 the nutrients of the flour fraction of the balance are set down.

Considerable thought and study has been given as to whether a different set of factors for the calculation of the nutrients in the flour should not be used for the year 1917-18 in view of the milling regulations which required, during the major portion of that year, a higher milling extraction of the wheat as flour than had prevailed before. It has finally been decided to use the same analytical factors for this as other years, because investigation showed that the new flour was so nearly identical in chemical composition with the old as not to make it worth while to take a different basis of

¹ Hereafter this publication will be referred to by the initials D.A.Y.B.

² Hereafter this publication will be referred to by the initials M.C.R.

computation so far as concerns analysis. We have, of course, made allowance for the higher quantitative extraction of the berry to flour in 1917-18.

It might at first thought be supposed that separate account should be taken of wheat used in breakfast foods. Consideration will, however, make it apparent that this is not necessary in the method here followed, because we have included *as flour* all the wheat which goes into these products, in our method of calculation. The only possible criticism which could be made on this point would be that the nutritive value of these breakfast foods is different from flour. The difference, however, is so small, and the total amount of wheat which goes into these products is so small as compared with what is consumed as flour that no statistically significant error is introduced by the method here used.

4. Oatmeal.—This item includes rolled oats and all other products of oats used as human food as well as oatmeal in the strict sense. There being no official statistics on the production of these commodities the data were collected *ad hoc* by the Statistical Division of the Food Administration from the Oat Millers' Association. Oatmeal being a derivative product used practically only as human food the whole output has been converted into nutrient values.

5. Barley Meal.—This rubric includes all products of barley used as human food. The production of barley flour, which is a new product in the United States manufactured in commercial quantities for general consumption (other than as baby food) only during very recent years, has become in that year a very significant item. The returns for the production of barley flour we have from the Milling Division of the Food Administration for a portion of the year 1917-18 and have made an estimate for the whole year's production from the known data. There being no official annual figures on the production of milled barley products resort has been had again to the quinquennial returns of the Census of Manufactures and a straight line fitted by least squares to the production figures there given for the years 1909 and 1914, and the estimated production of individual years read off the line, except in the case of 1917-18 as above explained. The barley products here dealt with being derivative products, used for human food only, the total production has been converted to nutrient values.

6. Rye Flour.—The same procedure and sources to arrive at annual estimates of production were adopted here as in the case of barley meal.

7. Buckwheat Flour.—The same procedure and sources were used for this commodity as for rye flour and barley meal and flour, except that in the case of buckwheat flour there appeared to be no good reason for any differential treatment of the year 1917-18.

8. Rice.—The crop figures, in terms of cleaned rice, were taken for the year 1911-12 and 1912-13 from D.A.Y.B., 1914, p. 590; for the years 1913-14 to 1915-16 inclusive from D.A.Y.B., 1916, p. 607; and for 1916-17 and 1917-18 from M.C.R., December, 1917, p. 117. From the total crop was deducted (a) 5 per cent. of the crop for wastage and spoilage, (b) the amount used as seed, and (c) the amount used in the manufacture of alcoholic beverages. The residue after these deductions was converted to nutrient values.

VEGETABLES

9. Beans.—Official estimates of the bean crop have been published by the Department of Agriculture only since 1914-15. In the years before that no data whatever were available. The figure for 1915-16 (M.C.R., Sept., 1916, p. 89) was for the 5 principal bean growing states only, New York, Michigan, Colorado, New Mexico, California. In later years returns from an additional state, Arizona, have been included. The figures given include, however, practically the whole of the commercial crop. The 1915-16 figure is from M.C.R., December, 1917, p. 127, and those for 1916-17 and 1917-18, *ibid.*, p. 117. For the years prior to 1914 we have estimated annual production figures to a rough approximation, on the general assumption that there has been no very violent change in bean husbandry as to acreage planted, methods of cultivation, or yield during the last 10 years, and that therefore the crops during the past 4 years make possible an approximate estimate for the three preceding years.

In all cases there has been made a deduction of one-fourth of the total crop before converting to nutrients, to allow for (a) seed and (b) wastage and spoilage in handling and storage, including effects of disease on nutritive values and usage, etc.

10. Peas (Other Than Canned).—The pea crop in the United States harvested as dry grain, as distinct from that harvested green for canning, is not large. Unfortunately the Department

of Agriculture until very recently has never collected statistics as to its amount. Consequently in order to get at any approximation to the amount of this commodity available for human food we are forced to make the best estimate possible from the published data for two years only. In M.C.R., May, 1918, p. 51, figures are given for the edible dried pea production in the five important producing states, Michigan, Wisconsin, Idaho, Washington, and Colorado, for the years 1916-17 and 1917-18. These states cover practically the whole of the commercial crop. Working from these figures and census returns as a basis, estimates have been made for the other years. In each case one-fourth of the estimated crop has been deducted for seed and losses in storage and handling. This deduction might seem large, at first thought, but it must be remembered that a fair proportion of the dried pea crop goes as seed for the green pea crop used in canning.

11. Potatoes.—The basic statistics for potato production were derived from the following sources: 1911-12 to 1915-16 inclusive D.A.Y.B., 1916, p. 614; 1916-17 and 1917-18, M.C.R., December, 1917, p. 117. From the figures as given in these sources we have deducted one-third of the crop in each year to allow for (a) seed and (b) spoilage and wastage. The residual values are then converted to nutrients.

12. Sweet Potatoes.—The crop statistics for sweet potatoes are given in D.A.Y.B., 1916, p. 617, for the years 1911-12 to 1916-17, inclusive. For 1917-18 the figure was taken from M.C.R., December, 1917, p. 117. A deduction of one-third of the crop is made in each year to allow for seed and spoilage and wastage in handling. The residue is converted to nutrient values.

13. Onions.—Statistics on the onion crop were first published by the Department of Agriculture for the year 1914-15. The sources of the data for that and following years are: 1914-15, M.C.R., November, 1915, p. 73; 1915-16, *ibid.*, August, 1916, p. 80; 1916-17 and 1917-18, *ibid.*, December, 1917, p. 117. The returns are for 13 states (12 in 1914-15) only, but cover practically the whole of the commercial crop. The crop of onions is highly variable in amount if one may judge from the four years for which figures are available. This makes estimating the crop of the missing years very difficult. The crops of the missing years, however, probably did not deviate far from the average of the four years for which data are available. On this basis, conservative estimates, erring almost surely in the direction of under-statement, have been

made for the three years 1911-12 to 1913-14, inclusive. In all cases a deduction of one-fourth of the crop has been made to allow for spoilage, loss in storage and transit, etc.

14. Cabbage.—Cabbage crop statistics were started by the Department of Agriculture first for the year 1914-15. The figures for that year are given in M.C.R., November, 1915, p. 73. For the year 1915-16 the reference is M.C.R., September, 1916, p. 92. The data for the last two years are given in M.C.R., December, 1917, p. 117. The statistics are for the crop produced in nine states, but cover practically the whole of the commercial crop. Before calculating the nutrients one-third of the estimated crop for each year is deducted for loss in storage and handling. On the basis of existing information for the last four years the three preceding years have been estimated.

15. Canned Peas.—The statistics for the production of canned peas were taken from "The Canning Trade Almanac of the Canning Industry, 1918" for the years 1911-12 to 1916-17, inclusive. The statistics are collected by the National Cannery Association under the personal supervision of the Secretary, Mr. Frank Gorrell. For the last year the production was reported to the Statistical Division of the Food Administration by each canner, and the statistics compiled by that Division. No deductions were made from the total production figures in calculating the nutrients. It should be understood that the canned pea pack does not nutritionally duplicate anything in the item "Dried Peas" given above. They are a separate and distinct production.

16. Canned Corn.—The sources and method of handling the data were precisely the same for canned corn as for canned peas above.

17. Canned Tomatoes.—The sources and method of handling the data were the same for this commodity as for canned peas and canned corn.

SACCHARINE MATERIALS

18. Beet Sugar.—This item includes the best sugar produced in the continental area of the United States. The sources of the statistics are as follows: for the years 1911-12 to 1915-16, inclusive, D.A.Y.B., 1916, p. 643; 1916-17 and 1917-18, M.C.R., July, 1918, p. 76. No deductions are made from this item in converting to nutrients. The carbohydrate content is taken as 100 per cent.

19. Domestic Cane Sugar.—This item includes the Louisiana cane sugars. It is given as a separate item because the carbohydrate

content of these sugars is less than 100 per cent. We have taken as a fair average carbohydrate content for all these sugars 95 per cent. No deduction from the production is made in calculating the nutrients. The source of the statistics is for the years 1911-12 to 1916-17, inclusive, M.C.R., May, 1917, p. 42; for 1917-18, Willett and Gray's Weekly Statistical Sugar Trade Journal, March 21, 1918, p. 128.

20. Molasses.—This item includes the molasses *produced in the United States* from sugars from the following sources: U. S. Cane, U. S. Beet, Hawaii, Porto Rico, and Cuba. The imports of sugar from the last three sources are computed in Chapter VI as *refined* sugar, and hence in counting the molasses as domestic production (which it is in the sense that it is made here) we are making no nutritional duplication. Molasses varies greatly in its sucrose content. As a fair general average we have taken the carbohydrate content of all molasses at 65 per cent. This is conservative, as Atwater and Bryant (p. 64) give the average as 69.3. We have lowered this because of Leach's (p. 568) data based on a larger number of analyses, showing a greater range of variation and a lower minimum value. (See also Henry and Morrison, p. 637.) Molasses is stated to have a "protein" content of from 2 to 4 per cent. Really, however, this is chiefly nitrogenous material not nutritionally available. Henry and Morrison (p. 186) say, regarding this point: "The crude protein of both beet and cane molasses consists largely of compounds having little nutritive value." It appears ridiculous in face of these facts to include the fairly large number of tons of protein which would result from applying the Atwater-Bryant factor to the total molasses production. We have accordingly called the protein and fat content of molasses zero. This gives a fuel value per pound of 1209 calories.

The statistics of production used were compiled by Mr. Joshua Bernhardt, the sugar statistician of the Statistical Division of the Food Administration, from information from a variety of trade and technical sources, and from Department of Agricultural figures. The really difficult problem with molasses is the proper allocation of the total crop between the following general classes of use, (a) human food, (b) stock feed, (c) industrial alcohol. On this point the advice of Dr. C. L. Alsberg, Chief of the Bureau of Chemistry of the Department of Agriculture, of Mr. George M. Rolph, Head of the Sugar Division of the Food Administration, and Dr. William Marshall, Controller of the International Sugar Committee,

has been obtained. The net result of our investigation of the matter is embodied in the following percentage allocation scheme, which has been made the basis of the deductions in the molasses item in Table 7.

	Per cent. to human food uses	Per cent. to stock feed	Per cent. to alcohol
Domestic cane.....	50	25	25
Domestic beet.....	0	50	50
Refiners' molasses and syrups.....	42	1911-14 32 1914-17 17	1911-14 26 1914-17 41

21. Glucose and Grape Sugar.—The figures on the production of liquid glucose and grape sugar were arrived at from information given in the Census of Manufactures and from a special questionnaire sent to glucose manufacturers at the request of the writer by Mr. George S. Mahana of New York. On this basis of information obtained from the manufacturers as to their sales, 4 per cent. of the production in each year was deducted for non-food industrial uses. An average carbohydrate content of 85 per cent. was assumed in the conversion to nutrient values.

22. Honey.—There are no official statistics of honey production. Dr. E. F. Phillips of the Bureau of Entomology of the U. S. Department of Agriculture, who has for many years been in charge of agricultural investigations, estimates that during the period covered by the present study 250,000,000 lb. fairly estimates the average annual production. We have accordingly adopted this figure. No deductions are made.

23. Sorghum Syrup.—This commodity is rather extensively used in the South as a sweetening agent. The production figures are from M.C.R., October, 1916, p. 102, for the years 1911-12 to 1915-16, inclusive, and from M.C.R., December, 1917, p. 117. The average carbohydrate content, as furnished by the Bureau of Chemistry, is 68.1 per cent.

24. Maple Sugar.—Statistics are available only for the census year, 1909, and for the years 1917-18 and 1918-19 (M.C.R., June, 1918, p. 61). From these data estimates have been made for the other years. No deductions have been made.

25. Maple Syrup.—The sources and treatment are the same as for maple sugar.

FRUITS

26. Apples.—The production statistics for apples were taken, for the years 1911–12 to 1915–16, inclusive, from D.A.Y.B., 1916, p. 635; for the years 1916–17 and 1917–18 from M.C.R., December, 1917, p. 117. Before calculating nutrient values one-third of the crop in each year was deducted for wastage and spoilage.

27. Peaches.—The statistics of production for this crop were taken from D.A.Y.B., 1916, p. 637, for the years 1911–12 and 1915–16, inclusive, and for the years 1916–17 and 1917–18 from M.C.R., December, 1917, p. 117. A deduction of one-third of the crop was made for spoilage and wastage.

28. Pears.—Statistics on the production of pears were only started by the Department of Agriculture in 1914–15. For that year the data were taken from M.C.R., November, 1915, p. 65; for the year 1915–16 from M.C.R., August, 1916, p. 80; and for the last two years from M.C.R., December, 1917, p. 117. The production in the years prior to 1914–15 was estimated from a fitted straight line. In each year one-third of the crop was deducted for wastage and spoilage.

29. Oranges.—Official statistics on the commercial production of oranges begin only in 1916–17 and were taken from M.C.R., December, 1917, p. 117. The production in earlier years has been estimated on the basis of the two known years and census returns in 1909. One-fifth of the crop is deducted for spoilage and wastage. It should be remembered that we are dealing here with statistics of a commercial pack and not with a total crop as in apples, some of which never even harvested, and consequently it is proper to make a smaller deduction than in the other fruits.

29a. Prunes.—The statistics of production of this, and the two following dried fruit crops, are taken from the California Annual, Vol. 2, No. 1, June 15, 1918. This is a publication of the California Packing Corporation. While the figures are trade rather than official estimates they are probably as accurate as other crop estimates. In any case they are the only data available on these crops.

29b. Raisins.

29c. Apricots, dried.

VEGETABLE OILS AND NUTS

Here we shall include as oils only cottonseed, corn, cocoanut, and olive oils. The other vegetable oils *produced* in this country are too small in amount in respect of human food use to be significant and detailed statistics regarding such minor items are largely

lacking. Furthermore it is possible to take account of the more important of them by the procedure followed with peanuts, where the fat content of the original crop is counted. It would be impossible accurately to divide the fat content of the peanut crop between peanuts as such and expressed oil, because of lack of sufficiently accurate and detailed statistics. But such procedure is wholly unnecessary because the whole fat content is accounted for by the method here used.

Other than the direct consumption as oil, the chief forms in which vegetable oils and fats are consumed as food in this country are oleomargarine and lard substitutes. Oleomargarine is carried as a separate item under Secondary Foods (cf. Chapter IV) and in the duplication of cottonseed and cocoanut oils which is thus brought about there is a safe allowance for the unenumerated minor oils. The chief vegetable oils used in lard substitutes are cottonseed, corn, and peanut oils, all of which are fully counted here.

30. Peanuts.—Peanuts constitute the only nut crop sufficient in magnitude to be significant in the nutritional sense. Official statistics on this crop have only been published by the Department of Agriculture during the past two years (M.C.R., December, 1917, p. 126). Before that time only census data are available. We have made estimates for the earlier years, on the assumption that the increase in the peanut crop was evenly distributed in time prior to 1916. In all cases 15 per cent. of the crop is deducted for seed and loss in harvesting, storage, and handling.

The distribution of the nutrient value of the peanut crop presents a difficult problem. Of the portion of the peanut crop actually *harvested* as grain, which is what the statistics here given refer to, comparatively little is fed to livestock,¹⁾ though a large proportion of the crop as *grown* is so fed.

The Fat and Oil Survey of the U. S. Food Administration furnishes figures on the peanut oil production. Working back from these figures the portion of the crop pressed for oil has been calculated. From this fraction of the crop there goes to human nutrition 75 per cent. of the fat content (data from Fat and Oil Survey) and none of the protein or carbohydrate. Of the balance of the harvested crop we have estimated that 90 per cent. of all the nutrient material goes to human food, and 10 per cent. to fodder. The nutrients, as they appear in Table 7, have been calculated on

¹⁾As we are informed by a practical Southern farmer of wide experience.

this basis. It is obvious that these are rough estimates, but it seems impossible to get more accurate information.

In the matter of analysis difficulty was experienced because of the wide discrepancies between published figures. Atwater and Bryant (p. 75) give a fat content of the whole nut, as purchased, of 29.1 per cent. This is obviously too low, as is evident from known facts as to the yield of peanut oil in crushing. Generally speaking the yield is 40 to 50 lb. of oil per 100 lb. shelled nuts.¹ Atwater and Bryant give the inedible refuse (shells) as 24.5 per cent. of total weight. It is then clear that nothing like the actual oil recoveries could be got from this 29.1 per cent. After thorough study of all the available analyses it has been decided to use throughout this book, the following figures for the nutrient content of whole peanuts with shell (unhulled) as purchased.

Protein.....	19.5 per cent.
Fat.....	67.1 } 33.2 per cent.
Carbohydrate.....	14.4 per cent.

These figures correspond to a commercial oil yield of 40 lb. per 100 lb. of peanuts with hulls removed, which is conservative.

31. Cottonseed Oil.—The basic statistics were the production of crude oil in each year as given in "Cotton Production and Distribution, Season of 1916-17" (Bureau of the Census, Bulletin 135, 1918), for all the years up to 1917-18. In this last year the total production was estimated from the known production to June 30, 1918. The crop year for cottonseed oil is from August 1 to July 31, inclusive. From the total crude oil produced was deducted in each year the amount used for non-food industrial purposes, chiefly soap-making. The balance remaining was converted to refined oil and the nutrient values calculated. The deductions for industrial uses were made on the basis of information contained in the Fat and Oil Survey.

32. Corn Oil.—The only available statistics on this product are given in the Census of Manufactures at quinquennial periods. A straight line was fitted by least squares to the 1909 and 1914 data and the other years read off from this line. The Fat and Oil Survey indicates that there is no appreciable quantity of *refined* corn oil used for non-food purposes, and therefore no deductions are made from the total production of refined oil here given.

¹ Johns, C. O. and Jones, D. B., *Proc. Nat. Acad. Sci.*, Vol. 3, p. 365, 1917. Also Armsby, H. P., "The Conservation of Food Energy," Philadelphia, 1918, p. 52.

33. Coconut Oil.—This is a product which has been manufactured in this country for edible purposes only in recent years. The figures for production were obtained from the Food Administration's Fat and Oil Survey and from the Bureau of Chemistry of the Department of Agriculture. Only the edible oil is taken account of. The much larger portion of the total production used for non-food industrial purposes is not included here.

34. Olive Oil.—The statistics for this commodity are derived from the Fat and Oil Survey of the U. S. Food Administration. Only the edible oil production is taken, and therefore no deduction is made for industrial uses.

FISH

35. Fish.—There are no official statistics as to the total catch of fish in this country. I have accordingly asked the U. S. Bureau of Fisheries to help in arriving at an estimate in this matter. After careful consideration they state that during the years covered by this study the best estimate they can make is that the average annual catch amounted to 2,000,000,000 lb., including all salt and fresh water fish, shell fish, etc., privately caught and locally consumed, as well as commercially caught. The figure also includes all canned fish.

In arriving at nutritional figures for this lump catch, it has seemed advisable to work with the edible portions only, deducting the refuse at one operation. For twenty-five leading varieties of fish and shellfish Atwater and Bryant's figures yield an average refuse percentage of 48.184. We have accordingly reduced the 2,000,000,000 lb. gross catch by this percentage. For the same twenty-five varieties we have determined the average analytical results for edible portion, as given by Atwater and Bryant, with the following results.

Protein.....	17.2 per cent.
Fat.....	3.9 per cent.
Calories.....	497 per lb.

These factors have been applied to the figures as given.

Table 6 gives in detail the conversion factors used. Since in this study conversions were first made to short tons of 2000 lb. the table is presented in that form. The results were then converted to metric tons by multiplying by the factor 0.9072.

TABLE 6.—FACTORS BY WHICH QUANTITIES IN THE SPECIFIED ORIGINAL UNIT OF MEASURE OF THE COMMODITIES NAMED ARE TO BE MULTIPLIED TO GET THE CONTAINED AMOUNT OF PROTEIN, FAT AND CARBOHYDRATE IN SHORT TONS OF 2000 LBS. * These conversion factors for wheat flour were used for all years except 1917-18. In that year, on account of the higher milling extraction, the factors became: Protein = 0.002531, fat = 0.000222, carbohydrate = 0.016672, calories = 0.073309.

** See text, p. 43, for treatment of peanut crop. The factors here given relate only to whole peanuts and are 90 per cent. of total nutrient values.

*** Calories calculated from final total nutrients as given in Table 7.

We come now to the consideration of Table 7 which gives the detailed results for primary foods.

It is not proposed to enter upon any detailed discussion of the results shown in Table 7 until certain other data are in hand, because to do so would inevitably involve unnecessary duplication. Here it is desirable only to summarize in convenient form for reference the data of Table 7. This is done in Table 8.

TABLE 8.—SUMMARY OF PRODUCTION OF PRIMARY FOODS
(Metric Tons)

Year	Total of all primary foods as commodity	Protein in primary foods	Fat in primary foods	Carbohydrate in primary foods	Calories (millions) in primary foods
1911-12	32,284,633	1,721,683	943,820	13,112,496	69,634,613
1912-13	37,974,989	2,003,254	922,136	14,957,522	78,152,802
1913-14	35,831,949	2,034,950	948,495	15,126,422	79,218,759
1914-15	42,354,173	2,327,578	1,092,610	17,063,873	89,706,981
1915-16	44,718,207	2,605,757	922,989	19,060,829	97,458,818
1916-17	33,059,677	1,777,138	925,363	13,678,245	72,012,140
1917-18	36,913,722	1,964,097	1,020,481	14,880,633	78,594,232
Total for 7 years.....	263,137,350	14,434,457	6,775,894	107,880,020	564,778,345
Average per year, whole period.....	37,591,050	2,062,065	967,985	15,411,431	80,682,621
Average per year, 3 prewar years.....	35,363,857	1,919,962	938,150	14,398,813	75,668,725
Average, war years.....	39,261,445	2,168,643	990,361	16,170,895	84,443,043
Per cent. nutrients to total (whole period) and calories per pound.....	5.5	2.6	41.0	97.4

The data of Table 8 are shown graphically in Fig. 3.

From the summary and Fig. 3 we note: first of all, that while the total production of primary foods generally increased up to the year 1915-16 it fell off badly in the two following years, 1916-17 and 1917-18, going back in 1916-17 to practically the level of the earliest of the prewar years here discussed. The yearly fluctuations are, however, much less violent in the nutrients than in the gross totals of commodities. This can best be demonstrated by reducing the figures of Table 8 to a relative basis, by taking the average of the whole period as 100, for each column, and then reducing each year figure to that relative base. This is done in Table 9.

The much smoother increase in the nutrients to the high point in 1915-16, as compared with the gross commodity total is apparent.

Protein shows the greatest percentage change, the production having increased 42 per cent. from 1911-12 to 1915-16. It also

FIG. 3.—Showing the course of production of primary food materials since 1911. Solid line denotes total primary food production. Dash line, protein content of primary foods, dot line, fat content of primary foods, dash-dot line, carbohydrate content of primary foods.

TABLE 9.—RELATIVE CHANGES IN PRODUCTION OF PRIMARY FOODS
(Seven Year Average = 100)

Year	All primary foods as commodity	Protein in primary foods	Fat in primary foods	Carbohydrate in primary foods	Calories in primary foods
1911-12	86	83	98	85	86
1912-13	101	97	95	97	97
1913-14	95	99	98	98	98
1914-15	113	113	113	111	111
1915-16	119	126	95	124	121
1916-17	88	86	96	89	89
1917-18	98	95	105	96	97

suffered most in the slump of 1916-17, dropping back 40 per cent. in one year from its highest point. The increase in calories amounts to 35 per cent. The greatest increase in fat production was from 1912-13 to 1914-15, amounting to 18 per cent., less than half of the increase in protein production. One might think that all the nutrients ought to change proportionately to each other and to the total crop. Thus it may puzzle one at first thought to understand why the nutrient production was higher for all three in 1913-14 than in 1912-13, while the total production of primary foods as commodity was 6 per cent. lower in 1913-14 than in 1912-13. The explanation for the apparent paradox is seen to be simple by examination of the separate items in Table 7. In 1913-14 the vegetables and fruits gave generally a lower production than in the previous year. But the grains were higher, and also the sugars and fats. Thus, while the decrease in the fruits and vegetables was sufficient to bring about a decrease in gross tonnage, the higher nutrient content of grains, fats, and sugars turned the nutrient scale the other way.

The year 1917-18 was below the general average of the whole period in all items of primary nutrient production except fat. The stimulation of high prices to the producer and great demand for vegetable oils, and the response of the people of the country to the request of the Food Administration to eat more cornmeal resulted in a notable increase in the net production of nutrient fat in the form of primary foods during the past year. The result is of great significance as indicating the possibilities of fat production from vegetable sources in this country under stress of necessity. To go into the matter a little more closely, it is seen that the total production of primary foods in 1917-18 was 1,113,974 metric tons *lower* than in 1912-13, a decrease of approximately 3 per cent. But in 1917-18 the net nutrient fat produced in the primary foods for human food uses was 113,274 metric tons *higher* than that produced in 1912-13. It thus appears in comparing these two years that with a 3 per cent. *smaller* total primary food production, there was a 12 per cent. *greater* production of net nutrient fat from the primary foods. Even this certainly does not represent the extent to which we might go, in dire necessity, in speeding up and extending the manufacturing processes which make available for human food the fat content of the primary crops.

With a single exception, 1917-18 shows the highest production of fat. The exception is 1914-15, when the cottonseed oil production was very high owing to a bumper cotton crop and brought up the total.

The last line of Table 8 is of interest in showing the net percentage nutrient content of all primary foods over the whole seven year period. From this line it is seen that, after making all due deductions for seed, invisible loss, etc., the net percentage of protein in the primary foods was 5.5, of fat 2.6 and of carbohydrate 41.4, with a fuel value of 935 calories to the pound. It should be understood that these percentages are *net*. Besides the general deductions from the commodities as explained above, allowance was made in calculating the nutrients for inedible refuse in preparing the foods for the table. Putting all the nutrients together it appears that of the net tonnage of primary food commodities produced in this country for human consumption only 49.5 per cent. has direct true nutrient value. The remaining 50.5 per cent. represents (a) water, (b) inedible refuse, and (c) ash.

The relation of the different primary food commodities to the total production of nutrients will be discussed in a later chapter.

CHAPTER IV

THE SECONDARY FOOD PRODUCTION OF THE UNITED STATES

(Commodity References Nos. 36-48)

In this chapter will be considered the production of the remaining materials used as human food in addition to the primary foods listed in Chapter III. Here again there are of necessity minor omissions, and in some cases we have had to resort to estimates because of lack of statistics. No account is taken of the production of meats through game, goats, rabbits or horses. None of these items is of any statistical significance in the nutrition of this nation, though in certain foreign countries each of them assumes some importance. Here it would be impossible to include these items in any case because of lack of information.

Just as in Chapter III it will be necessary to give a detailed explanation of how the figures on each item were obtained. The reference numbers to items will continue serially from those in Chapter III.

In Table 11 are given data as to the domestic production of the following commodities:

MEATS AND DERIVATIVE PRODUCTS

36. Beef.—The data here include the total production of what is technically known as carcass beef. This means the meat and fat of the dressed carcass. This item does not include (a) the visceral fat, from which oleo oil is made and which is accounted separately for in the oleomargarine and in the oleo oil produced for export, or (b) the edible offal, liver, tongue, etc.

To arrive at total production the starting point was the statistics of slaughter of cattle under federal inspection, published by the Bureau of Animal Industry of the U. S. Department of Agriculture. It was assumed that the percentage of inspected slaughter to the total slaughter in the whole country was the same as that found at the last census (56.39 per cent.) for all years up to 1916-17. It is known that during the past two years there has been a marked

change in this percentage. After careful consideration the following estimates were made:

Year	Percentage of inspected slaughter to total
1916-17.....	63
1917-18.....	72

The number of animals slaughtered, as above calculated, was then multiplied by the average live weight per animal for the same year, as determined at the Chicago packing establishments.¹ This gave the total live weight slaughtered. There may be some criticism of using Chicago average live weights rather than those from some other point or points but, on the whole, it seemed wisest to use the Chicago figures for the reason that it is the largest market and, over a period of years such as we are here dealing with, probably the most representative. Having arrived at total live weight figures 52.5 per cent. of these was taken as representing dressed weight.

In obtaining the nutritive values Atwater and Bryant's (p. 28) figures for "Sides, All analyses" were used, taking the "As purchased" values, which as already explained (p. 33) make allowance for inedible refuse as a part of the analysis.

37. Edible Offal from Cattle.—In obtaining the edible offal figures 2.9 per cent. of the live weight as given under Reference No. 36 was taken to represent the production of these products. This percentage figure was calculated from data reported by the packers.

To obtain the nutritive value of the edible offal Atwater and Bryant's figures for the following organs were averaged: brain, heart, kidneys, lungs, marrow, sweetbreads, suet and tongue. In making the average each organ was allowed to count roughly in proportion to its weight. The final weighted average analysis of beef offal "as purchased" was as follows:

Protein.....	16.0 per cent.
Fat.....	14.9 per cent.
Carbohydrate.....	1.0 per cent.
Calories.....	945 per lb.

The carbohydrate is, of course, glycogen in the livers.

¹ I wish to acknowledge my great indebtedness to the various Chicago packers, particularly Armour & Co., for furnishing much needed data on various points connected with this analysis of meat production. For many points no official statistics are either collected or published, and the books of the packers are the only source of information.

38. Veal.—In principle the method of arriving at production figures for veal was the same as that used for beef. Starting with inspected slaughter the census percentage of 33.46 per cent. inspected to total slaughter was applied for all years up to 1916-17. For 1916-17 a percentage of 45 was assumed, and for 1917-18 a percentage of 50. The number of animals slaughtered, as above determined, was multiplied by the average Chicago live weight for each year. The percentage of dressed weight to live weight was taken at 62.11 per cent. The analytical figures for sides as purchased were used.

39. Edible Offal from Calves.—The edible offal for calves was taken at 5.23 per cent. of the live weight on the basis of packers' reports. The nutritive values of the offal were computed on the same plan as that employed for beef edible offal, with the following weighted average analytical results:

Protein.....	17.3 per cent.
Fat.....	6.1 per cent.
Carbohydrate.....	0.0 per cent.
Calories.....	576 per lb.

40. Pork and Lard.—Here the percentage of inspected to total slaughter is taken for all years at 58.86 per cent. there being no evidence of any significant change in this respect in recent years. The average percentage of dressed weight to live weight is taken at 71.97 per cent. for all years, on the basis of packers' reports. This dressed weight percentage *includes the lard* produced from the carcass, along with the pork, so that lard is not set down as a separate item in Table 11. The analytical figures used were those for "Side, lard and other fat included as purchased" (Atwater & Bryant, p. 39).

41. Edible Offal from Hogs.—Packers' reports indicate the edible offal to be 5.559 per cent. of the live weight. This figure was accordingly used. For the analytical constants we have again made a weighted average of the organs included, with the following results:

Protein.....	18.4 per cent.
Fat.....	8.8 per cent.
Carbohydrate.....	0.8 per cent.
Calories.....	732 per lb.

42. Mutton and Lamb.—Here the percentage of inspected to total slaughter is taken at 76.95 for all years. On account of the inclusion here in one group of old and young animals it was thought desirable to get the dressed weight in a different manner than in the other cases. Through the kindness of Armour & Co., we were able to get average absolute dressed weights from all their plants and these absolute weights were applied to total slaughter. The analytical figures used were for sides as purchased, including tallow.

43. Edible Offal from Sheep and Lambs.—The percentage of edible offal here, from packers' reports, is 2.77 per cent. of the live weight. The weighted average analytical constants used are:

Protein.....	19.8 per cent.
Fat.....	8.9 per cent.
Carbohydrate.....	2.8 per cent.
Calories.....	796 per lb.

44. Oleomargarine.—The statistics on the production of oleomargarine were obtained from the "Annual Report of the Commissioner of Internal Revenue for the Fiscal Year Ending June 30, 1917" (p. 150) for all years up to 1917-18. The production for 1917-18 was estimated on the basis of monthly returns from the Commissioner of Internal Revenue through April, 1918.

As already explained (p. 43 *supra*) this item involves some nutritional duplication, in respect of the vegetable oils which oleomargarine contains. This duplication is allowed to stand in order to correct in the total for the omission of minor vegetable oils from the primary foods.

45. Oleo Oil for Export.—This item is inserted here as well as in the export table on the following reasoning. Oleo oil is made from the visceral and caul fat of beef, which is not included in the dressed weight of beef in Table 11. That portion of the oleo oil which is domestically consumed is used in making oleomargarine and its production is accounted for in Item 44 above. But if we did not insert here the oleo oil which is exported as such, we should be short on the production side of the ledger by just that amount. It is not an insignificant item, and therefore it has been inserted here. The data are from the successive numbers of the Monthly Summary of Foreign Commerce issued by the Department of Commerce. The same item appears unchanged in Table 37, Chapter VII, among other exports.

POULTRY AND EGGS

46. Poultry.—Unfortunately there are no annual statistics as to either amount of poultry on farms, or production of poultry. Consequently we have had to estimate this item. This has been done after consultation with the Animal Husbandry Division of the Department of Agriculture. The best that can be done is an estimate of the annual production of all sorts of poultry. The values given are arrived at partly from Census figures and partly from an assumed annual increase, accompanying the increasing population of the country and the steady and intensive propaganda on the part of the Department of Agriculture, the Agricultural Experiment Stations, and the Colleges of Agriculture for more and better poultry.

An average live weight of 3 lb. per head is assumed. This seems reasonable when it is remembered that the total includes everything from turkeys and geese to broiler chicks.

Because of the heterogeneous inclusiveness of the item the question of proper analytical factors is a difficult one. It has been approached from the general angle of weighting the analyses of Atwater and Bryant for the different sorts of poultry, broiler chicks, fowls, turkeys, etc. in roughly the proportion that the specified kind of poultry is marketed, and then taking a weighted average analysis to apply to the lump production figure. In determining the weighting factors the writer has ventured to allow himself to estimate them on the basis of his own fairly long and intimate acquaintance with the poultry industry in this country. The refuse percentage in preparing poultry for the table is large—from 20 to 40 per cent. in Atwater and Bryant's computation. This explains in part why the total contribution to the nutrition of the nation by poultry is so comparatively small.

The weighted mean analysis used in calculating nutrients is as follows:

Protein.....	13.3 per cent.
Fat.....	9.3 per cent.
Calories.....	639 per lb.

47. Eggs.—Again annual statistics are lacking, and an estimate has to be made on the basis of Census returns. In 1909 the Census estimated the number of eggs produced in the year at 1,591,311,371

dozen. The Animal Husbandry Division of the Department of Agriculture is of the opinion, with which the writer agrees, that owing to better methods of husbandry the productivity per fowl has been rising somewhat since 1909. They suggest that in recent years an annual production of 1,875,000,000 dozen probably represents the facts. The production in 1917-18 was unquestionably lower than in the previous year, due to high prices for feed on the one hand, and for poultry on the other hand. On the basis of the above consideration I have estimated annual production figures as shown in Table 11. The average weight of eggs was taken at 1.5 lb. per dozen.

DAIRY PRODUCTS

48. Dairy Products (as Milk).—Under this rubric are included all the dairy products, milk, butter, cheese, etc. It is possible to get a much more accurate result by handling the matter in this way than would be the case if one attempted to separate the several items. All are expressed in terms of milk.

To obtain the production of milk it is assumed that each cow, as enumerated each year under the rubric "Dairy Cows" by the Bureau of Crop Estimates of the Department of Agriculture, produces on the average 154 lb. of butter fat in the year. This estimate is one which is agreed to by the Dairy Division of the Department of Agriculture and is probably very close to the truth. Multiplying this average annual production by the number of dairy cows gives the total production of butter fat. It is next assumed that the milk will average to test 3.6 per cent. fat. This estimate may be a little high, but it cannot be far from the fact. This leads to an average milk production per cow of 4278 lb. per year.

As to the nutritional distribution of the product it is assumed that 96 per cent. of the fat content of the milk, and 50 per cent. each of the protein and carbohydrate content go to human food uses. Of the remainder it is assumed that 3 per cent. of the total fat and 40 per cent. each of the total protein and carbohydrate contents go to animal feed; in the form of skim milk, butter milk, and milk sucked by calves. The residue (1 per cent. of the total fat content, and 10 per cent. each of protein and carbohydrate contents) is assumed to be lost, wasted, and used for non-food industrial purposes.

The conversion factors, by which commodities in units given are

converted to short tons of protein, fat and carbohydrate, are given in Table 10. Values in short tons obtained by the application of these factors are converted to metric tons by multiplying by 0.9072.

TABLE 10.—FACTORS BY WHICH QUANTITIES (IN SPECIFIED ORIGINAL UNIT OF MEASURE) OF THE COMMODITIES NAMED ARE TO BE MULTIPLIED TO GET THE CONTAINED AMOUNT OF PROTEIN, FAT AND CARBOHYDRATE IN SHORT TONS OF 2000 LB. SECONDARY FOOD PRODUCTION OF THE UNITED STATES 65

In Table 11 are given the data as to the production of secondary foods in the United States. The arrangement of the table is the same as that of Table 7 for the production of primary foods.

* Excluding deductions as per text.

Since at this point we are concerned only with the presentation of basic data, detailed discussion of the results set forth in Table 11 will be deferred to a later chapter. Before passing to the next phase of the subject, however, it is of interest to compare the total secondary food production in the successive years covered. This is done in Table 12 and in Fig. 4.

TABLE 12.—SUMMARY OF PRODUCTION OF SECONDARY FOODS
(Metric Ton)

Year	Total of all secondary foods as commodity	Protein in secondary foods	Fat in secondary foods	Carbohydrate in secondary foods	Calories (millions) in secondary foods
1911-12	50,644,020	1,969,827	4,622,089	888,562	54,753,902

Total for 7 years.....	368,541,782	14,121,976	33,383,169	6,501,418	395,366,897
Average per year, whole period.....	52,648,826	2,017,425	4,769,024	928,774	56,480,985
Average per year, 3 prewar years.....	50,262,836	1,934,642	4,522,016	886,084	53,667,284
Per cent. nutrients to total (whole period) and calories per lb...	3.8	9.1	1.8	487

The data of Table 12 are shown graphically in Fig. 4. They are reduced in Table 13 to relative figures by taking the average of the whole period for each column as 100 and reducing each year to that base.

TABLE 13.—RELATIVE CHANGES IN PRODUCTION OF SECONDARY FOODS
(Seven Year Average = 100)

Year	All secondary foods as commodity	Protein in secondary foods	Fat in secondary foods	Carbohydrate in secondary foods	Calories in secondary foods
1911-12	96	98	97	96	97
1912-13	95	96	95	95	95
1913-14	95	94	93	96	93
1914-15	99	99	101	98	100
1915-16	102	102	104	102	104
1916-17	106	106	105	106	105
1917-18	107	105	105	108	106

It is evident that the production of secondary foods is a more stable matter than the production of primary foods. The maximum fluctuation in the relative figures of Table 13 amounts to only 12 or 13 points in any nutrient or the total production. This would, on the whole, be expected because of the fact that animal produc-

FIG. 4.—Showing the course of production of secondary food materials since 1911. Solid line denotes total secondary food production; dash line, protein content of secondary foods; dot line, fat content of secondary foods; dash-dot line, carbohydrate content of secondary foods.

tion operates from a base which is much more nearly perennial than crop production and is also less influenced by small environmental changes. The growth and production of a herd of cattle or hogs is less affected by unfavorable weather conditions in a particular season than is a crop of wheat, for example.

A second point which strikes one at once in comparing secondary

with primary food production is that, during the period of time here under discussion, the maximum productivity is attained in different years in the two cases. The maximum of gross production of secondary foods is reached in the last year of the period, 1917-18. The same is also true of all the separate nutrients except protein, which falls in 1917-18 a little behind the 1916-17 production. The maximum primary production was, as we have seen earlier, in 1915-16.

The last line of Table 12 shows that of the 368,541,782 metric tons of secondary foods produced in the seven years, which amount is the residue after all necessary deductions, 3.8 per cent. net was protein available for human nutrition, 9.1 per cent. fat and 1.8 per cent. carbohydrate. Or, put it another way, all the net nutrients in secondary foods, after allowing for inedible refuse, amount to but 14.7 per cent. of the total net tonnage of such foods. The remaining 85.3 per cent. represents (a) water, (b) inedible refuse and (c) ash. These figures, in comparison with the similar ones for primary foods given in the preceding chapter, show at once how different in a physiological sense the secondary foods are from the primary. The great outstanding function of the secondary foods is to supply fat in a form relished by human beings. Further of course these foods play an important rôle in supplying body building protein and vitamins.

CHAPTER V

TOTAL HUMAN FOOD PRODUCTION]

Having now completed the survey of the production of primary and secondary food materials separately, it is desirable to combine the two and put the material in such form as to make possible certain general conclusions regarding the total production of human food in this country. At the outstart it needs to be again made clear exactly what the figures signify. As explained in the text of Chapters III and IV, in detail, the total production in metric tons means, in case of each commodity, the net production of that commodity *available for human food*, after deductions for seed, spoilage, animal feeding, industrial uses, etc. The nutrient production figures show, for each commodity, the net amount of protein, carbohydrate, fat, and calories, which can be got as human nutrients out of the total produced, after allowing for the inedible refuse which was still included in the total commodity production figures, even after the general deductions described above had been made.

It will be of interest to consider first the results in the mass. Table 14, which is a combination of Tables 8 and 12, shows the total production of human food in each year covered in this study and the percentage contribution of primary and secondary foods to this total.

The total production of human food within the period under consideration increased rather steadily to a maximum point in 1915-16 and then fell off in the last two years. The same course was true of protein, carbohydrate and calories. The fat production followed a different line, reaching a maximum in 1917-18.

Comparing the four war years with the three prewar years, it is seen that the average annual production had been definitely greater in the war period. The absolute and percentage amounts of the increase are shown in Table 15.]

TABLE 15.—EXCESS OF AVERAGE ANNUAL HUMAN FOOD PRODUCTION DURING WAR PERIOD

Item	Excess of annual average war production over prewar	Per cent. increase
Total human food.....	8,073,070 metric tons	+ 9.43
Protein.....	393,551 metric tons	+10.21
Fat.....	484,474 metric tons	+ 8.87
Carbohydrate	1,846,990 metric tons	+12.08
Calories.....	13,698,295 millions	+10.59

FIG. 5.—Diagram showing relative increase in average annual human food production in the war years as compared with prewar. The prewar annual average is taken as 100 per cent. (black bar) and the war annual average is shown as a cross hatched bar.

The greatest average annual increase is in carbohydrate, then follow calories and protein close together. Fat production shows

the smallest relative increase over prewar conditions. In general the war years show about 10 per cent. increase in production of human food over the prewar. This result is shown graphically in Fig. 5.

This increase in production of food in the United States during the four war years is the result of two circumstances: first, favorable crop conditions in the first two years of the war, and second, heavy export demand with associated high prices, which led the farmer to plant large acreages. That the second of these factors alone will not suffice to bring about increased production, unless the first is present, is shown by the conditions in 1917-18, when the production fell off badly in the face of the highest prices known for many years for farm products.

It is instructive in this connection to compare 1917-18, our first year in the war as a combatant, with the three preceding war years. Owing to the fact that this country was actively involved and that furthermore the need on the part of the Allies for food from America was greater than in any prewar year of the war, there was every incentive to an increased production. But the fact is that production in 1917-18 fell distinctly below the average of the three preceding years 1914-15 to 1916-17, inclusive, for all items except fat. This is shown in Table 16.

TABLE 16.—TOTAL FOOD PRODUCTION IN 1917-18 AS COMPARED WITH THE THREE NEXT PRECEDING YEARS

Item	Change in 1917-18 production as compared with average of 3 preceding years	Per cent. increase or decrease
Total human food.....	- 692,941 metric tons	-0.74
Protein.....	- 214,794 metric tons	-4.99
Fat.....	+ 141,460 metric tons	+2.39
Carbohydrate.....	-1,669,361 metric tons	-9.51
Calories.....	-6,407,392 millions	-4.43

The results in this table are extremely interesting from a nutritional standpoint. It appears that while the gross total production of food in our first year in the war was only insignificantly smaller (0.8 per cent.) than the average of the three preceding war years, we were short 5 per cent. in protein, and nearly 10 per cent. in carbohydrate. In total calories we were 4.5 per cent. short. Only

in fat was the 1917-18 human food production as great as in the three preceding years, and there the excess was only 2.4 per cent. Following the lean year 1916-17, which depleted all reserves nearly to the vanishing point, it is clear that during our first year in the war our food problem was a real one. Only by a reduced domestic consumption and the most widespread and rigid conservation could there be any hope of meeting a normal export program. In later chapters the facts regarding consumption and export will be presented.

The next point to which attention may be turned is the proportionate contribution of primary and secondary foods to the total nutritional production. Taking the whole seven year period together it is seen that while only 42 per cent. of the total tonnage of human food production is primary and 58 per cent. secondary, 51 per cent. of the protein, 94 per cent. of carbohydrates and 59 per cent. of the fuel value come from the primary foods, which are of course chiefly of plant origin. The secondary or animal foods make their large contribution in fat, furnishing 83 per cent. of the total. Protein for human food is produced about equally from plant and animal sources. If we put fish, here classed as a primary food source because no feed is expended in its production, with the other animal foods the protein balance in production would be thrown definitely to the animal side.

Altogether Table 14 is an impressive object lesson to those tending to belittle the importance of foods of animal origin in the national nutrition. Any source which contributes, in fact, about half the protein and half the calories, and nearly 85 per cent. of the fat produced in the country, cannot safely be treated in a step-motherly manner, if the proper nutrition of the nation is to be maintained. Furthermore these facts would appear to give little comfort to the vegetarian cult. The United States is a reasonably healthy nation, as populations go. This condition of health is maintained on a diet in which animal products contribute very substantial amounts, as has been seen.

The figures of Table 14 also demonstrate in a striking manner what a vast quantity of raw materials has to be grown to yield a sufficient amount of nutrients. Summing the percentages of the last line of Table 14 it is seen that only 29.0 per cent. of the total tonnage of human food materials produced is net nutrients. The remaining 71.0 per cent. of the total tonnage is made up of water,

ash, and inedible refuse. What this means may be made clear by a comparison. Suppose one found that 71.0 per cent. of his winter's coal supply was slate and stones which would not burn, and only 29.0 per cent. was real coal which would burn. That situation would exactly parallel that of the material used to stoke the human furnace. These facts are shown graphically in Fig. 6, in such way as to show the net nutrients and wastage in the total and in primary and secondary human foods.

FIG. 6.—Diagram based on Table 14 to show graphically the net nutrients in human food, of primary and secondary origin. Cross-hatched areas represent primary foods, and stippled areas secondary foods.

The next point to which attention may be turned is that of the relation of production to population. Many years ago Malthus argued that population always tends to outrun subsistence. It is of course clear at once that in a food-exporting country like the United States subsistence is still far ahead of population, but it is desirable to set forth here the facts as to per capita production during the period covered by the study.

The population of continental United States, as estimated by the Bureau of the Census for January 1 of each year (the mid-point of the fiscal years used in this study) is shown in Table 17.

TABLE 17.—POPULATION OF CONTINENTAL UNITED STATES

Year	Population, January 1
1912	94,736,339
1913	96,354,333
1914	97,972,327
1915	99,590,321
1916	101,208,315
1917	102,826,309
1918	104,444,303

Table 18 shows the total per capita *production* of human food materials in the successive years. It must be clearly remembered that these are gross *production* figures, *not* consumption statistics. Those will be presented later.

TABLE 18.—HUMAN FOOD PRODUCTION PER CAPITA PER YEAR IN THE UNITED STATES

Year	Foods as commodities per capita, kg.	Protein per capita, kg.	Fat per capita, kg.	Carbohydrate per capita, kg.	Total nutrients per capita, kg.	Calories per capita (millions)
1911-12	875.4	39.0	58.8	147.8	245.6	1.3130
1912-13	913.1	40.9	56.5	164.4	261.8	1.3680
1913-14	877.5	40.2	54.8	163.5	258.5	1.3453
1914-15	946.9	43.4	59.3	180.5	283.2	1.4702
1915-16	974.4	46.2	58.0	197.7	301.9	1.5407
1916-17	862.7	38.0	57.9	142.6	238.5	1.2795
1917-18	892.2	39.1	57.9	152.0	249.0	1.3235
Annual average whole period.....	906.1	41.0	57.6	164.1	262.7	1.3773
Annual average 3 prewar years...	888.7	40.0	56.7	158.6	255.3	1.3423
Annual average war period.....	918.5	41.6	58.3	167.9	267.8	1.4021

It is evident from this table that there is as yet no occasion for worry along Malthusian lines in this country, so far as subsistence is concerned. Not only do we produce more food than we consume, but there is no definite falling off in the ratio between subsistence

produced and population. There were more total nutrients per capita produced in human foods in 1917-18 than in 1911-12. Furthermore the annual average production of all nutrients, separately and combined¹, was distinctly higher during the war period than before the war.

We may turn now to one of the most interesting points in the whole study, namely the relative nutritional importance of the productions of different commodity groups and single commodities. In making an analysis of this point it is desirable to get as long a time base as possible, in order to eliminate the effect of fluctuations in the crops in individual years. Consequently averages for the whole period of seven years have been used throughout. Tables 19 and 22 give the annual average nutritional content of each of the several primary and secondary human food groups. These seven year averages are first stated in absolute figures (metric tons) and then as percentages of the total. Finally the percentages are cumulated.

TABLE 19.—ANNUAL AVERAGE AMOUNT OF PROTEIN PRODUCED IN THE FORM OF PRIMARY AND SECONDARY HUMAN FOODS, ARRANGED BY COMMODITY GROUPS

Group	Total protein (metric tons)	Per cent. of total protein	Cumulated per cent.
Grains	1,698,456	41.64	41.64
Meats	1,013,773	24.85	66.49
Dairy products	755,861	18.53	85.02
Poultry and eggs	247,789	6.07	91.09
Vegetables	218,382	5.35	96.44
Fish	80,852	1.98	98.42
Oils and nuts	44,559	1.09	99.51
Fruits	19,362	0.48	99.99
Sugars	454	0.01	100.00
Total	4,079,488	100.00	

TABLE 20.—ANNUAL AVERAGE AMOUNT OF FAT PRODUCED IN THE FORM OF
PRIMARY AND SECONDARY HUMAN FOODS, ARRANGED BY COMMODITY
GROUPS

Group	Total fat (metric tons)	Per cent. of total fat	Cumulated per cent.
Meats.....	3,166,785	55.20	55.20

Fruits.....	2,488,099	1.81	99.62
Fish.....	515,051	0.38	100.00
Total.....	137,163,605	100.00	

The data from these tables are exhibited graphically in Fig. 7.

FIG. 7.—Diagrams showing the relative importance of the different main groups of human foods, in the production of nutrients in the United States.

The results of these tabulations are of interest and significance from the standpoint of national nutrition. Taking first protein we see that approximately 85 per cent. of our total production of protein for human food purposes is contained in the three commodity groups, grains, meats and dairy products. Of the remainder 11.5 per cent. is produced in two groups, viz., poultry and eggs, and vegetables. Nearly 42 per cent. of the total protein produced in human foods in this country is derived from the grains and 25 per cent. from the meats.

Approximately 92 per cent. of the nutrient fat produced in the form of human foods comes from three sorts of commodities; namely, meats with 55 per cent. of the total, dairy products with 25 per cent. of the total, and oils and nuts with 12 per cent. of the total.

Ninety-one per cent. of the carbohydrates are produced in the grains, sugars and vegetables, with the grains preëminent (72 per cent. of the total).

In the total production of energy values (calories) in human food the grains are again outstanding, with 42 per cent. of the total. With meats and dairy products they make up 81 per cent. of the total calory production. Oils and nuts and sugars stand on approximately an equal basis, with about 5 per cent. each.

Altogether it is plain that in the production of human foods in this country, grains, meats and dairy products are the most important sources, in the order named. Outstandingly the United States is a grain producing nation.

Let us turn next to a consideration of the relative nutritional importance of the production of individual commodities used as human food. The data are given in Tables 23 to 26 inclusive. These tables are drawn up on the same plan as those for the commodity groups just examined. Seven year annual averages were made from the earlier basic tables for each commodity. These means are then arranged in descending order of importance, first in absolute and then in percentage terms.

TABLE 23.—ANNUAL AVERAGE AMOUNT OF PROTEIN PRODUCED IN EACH PRIMARY AND SECONDARY HUMAN FOOD

Order	Commodity	Total protein (metric tons)	Per cent. of total protein	Cumulated per cent.
1	Wheat (nutrients in flour).....	1,407,230	34.50	34.50

THE NATION'S FOOD

FIG. 8.—Diagram showing the relative importance of the different human food commodities in the production of protein in the United States.

FIG. 9.—Diagram showing the relative importance of the different human food commodities in the production of fat in the United States.

FIG. 10.—Diagram showing the relative importance of the different human food commodities in the production of carbohydrate in the United States.

FIG. 11.—Diagram showing the relative importance of the different human food commodities in the production of energy values (calories) in the United States.

Figures 8 to 11 inclusive are diagrams based on Tables 23 to 26. The bars show the relative importance of the several commodities in respect of production.

The outstanding position of wheat in the human food production of this country is the most striking feature of these tables. It stands first in the production of protein, carbohydrate and calories, and fifth in the production of fat. No other raw material source of human food stands near it in general importance. These tables show very clearly why it is that so much stress was laid upon this commodity in connection with the food factor in winning the war. Even though the claim be allowed that there are plenty of other foods just as good as wheat the fact still remains that in bulk significance in the production of human nutriment in this country wheat stands in a class by itself. The energy content of the wheat crop is nearly double that of its nearest competing commodity. The same is true of the protein content, while in carbohydrate content the average net wheat crop for human consumption is about 6 times as great as that of the closest competing commodity. About 2 per cent. of all the fat for human nourishment produced in this country is in the wheat crop.

Next to wheat in all round nutritional importance from the production standpoint in this country comes the hog. This lowly creature stands far and away ahead of any other source in the production of fat for human nourishment, with over 42 per cent. of the total production of this nutrient to its credit. It stands fourth in the production of protein, and second in the production of total energy values.

The third outstanding producer of human nutriment is the dairy cow. She stands second in the production of protein and fat, fourth in the production of carbohydrate, and third in energy value. If we take into account the nutritional significance of the dairy products in the broadest sense, including a valuation of the growth promoting substances of milk, it would probably be correct to place the dairy cow ahead of the hog as a contributor to our food resources. Leaving further discussion of this point aside, however, until we have consumption figures in hand, it is entirely clear that the wheat crop, the hog, and the cow together comprise our great reservoir of human nutrients. Together they produce 62 per cent. of all the protein and carbohydrate used as human food, 69 per cent. of all the fat, and 65 per cent. of all the calories.

The second most striking feature of Tables 23 to 26 consists in the fact that only a comparatively few commodities are at all significant individually in the total nutrient production of the coun-

try. In the case of protein there are only 12 commodities which individually contribute as much as 1 per cent. to the total production, and only 8 that contribute as much as 2 per cent. The total fish catch, for example, furnishes less than 2 per cent. of the total protein produced in the country. There are only 11 commodities individually contributing as much as 1 per cent. of the total fat produced for human food. The same is true of carbohydrate production, of which there are 12 commodities each contributing 1 per cent. or more to the total energy production.

These facts make it evident that any campaign for increased food production, to be really effective in a nutritional sense, must be concentrated on a very few of the great staples. Even if one multiplied the onion crop, for example, by such a practically impossible amount as ten fold it would still contribute something less than 1 per cent. of the total calory production in the form of human foods. The United States Department of Agriculture has showed great wisdom during the war in concentrating its production campaign chiefly on wheat and hogs.

Another point in the same connection relates to the home garden movement. That it was and is in every respect a highly laudable, patriotic, and to some extent economical thing for everyone who can do so to grow food in his back yard, goes without saying. But the public is prone to over-estimate the nutritional significance of this sort of activity. When it is remembered that the *total commercial production* on the farms of the country of sweet potatoes, beans, peas, onions, cabbage, and of corn, peas, and tomatoes for commercial canning, amounts *altogether* to only 2 per cent. of the total calory production in human foods, and further when one recalls that the home garden production of vegetables cannot possibly be more than a very small fraction of the commercial production of vegetables, it is clear that the home gardens can contribute to the total nutritional resources of the country only an extremely insignificant bit.

Again, the poultry industry considers itself, and rightly so, an important enterprise in the welfare of the country. But considered objectively as a nutritional resource, poultry and eggs together contribute less than 2 per cent. of the total production of calories in human food, only about 6 per cent. of the total protein, and about 3 per cent. of the fat.

Of the vegetables the potato is the only one which makes, by

itself, any particularly significant contribution to our food resources. This crop makes up about 3 per cent. of the total protein production, nearly 6 per cent. of the total carbohydrate production, and a little over 3 per cent. of the calorie production.

Taking all the data of Tables 23 to 26 together it is clear that the statistics on human food production given in this and the preceding chapters must be within 2 or 3 per cent. of absolute completeness, from the nutritional point of view. For the minor crops which are here omitted obviously produce far less net nutrient material than those listed in the last half of Tables 23 to 26. But the last 24 commodities listed in Table 26 contribute *all together* less than 3 per cent. of the total energy value of the 48 human foods listed. And these last 24 items include such crops as fish, veal, peas, onions, cabbages, oranges, peaches, etc. It is obvious that the omission of such things as strawberries, blueberries, mushrooms, cucumbers, celery, home garden vegetables, etc., cannot possibly have affected significantly the net result.

In concluding this chapter I wish to emphasize once more what was said at the beginning, lest there may be any misunderstanding on the reader's part; namely, that in this chapter we have dealt with figures of *production* only, not consumption, and of *human foods* only, not feeds or fodders.

CHAPTER VI

GROSS IMPORTS OF PRIMARY AND SECONDARY FOODS

(Commodity Reference Nos. 49-97)

Having dealt with the production of human foods in the United States we turn, as the next step in the analysis which will finally end in consumption statistics, to a consideration of the human food materials which come into this country in the way of imports. Here the basic statistics are those of the Department of Commerce.¹ Included in the food imports as here given are the shipments of food materials from Porto Rico and Hawaii to the United States. Those from Alaska are allowed for in production (fish) and those from the Philippine Islands are included in the Department of Commerce import figures.

The present chapter deals with gross imports only, and in consequence no deductions are made here for industrial uses and the like from the gross imports as given by the Department of Commerce. When later we come to apply *net* imports and exports to the determination of consumption, proper deductions for the factors mentioned will be made.

Unfortunately it has not been possible to include every item of foodstuffs imported, for the reason that the import statistics of certain minor items are given in values only and not in pounds or other unit of quantity. It would be an extremely hazardous procedure to attempt to convert values to quantities on these items, particularly for earlier years. Hence it has seemed wisest to leave such items out of the tables altogether. In any case they are insignificant nutritionally. A few other items such as mushrooms and truffles, were omitted because of their slight nutritional significance.

In a few cases it has been necessary to estimate the imports for the earlier years, because in those years the figures for these particular commodities were not separately stated in the reports of the

¹ Monthly Summary of Foreign Commerce of the United States, Department of Commerce, Bureau of Foreign and Domestic Commerce.

Department of Commerce. Instead they were then included in some general "all other" class. In making such estimates the guide has been the importation in the years when it was definitely known.

The gross imports, under the same general classifications as were used in Table 7, Chapter III, of primary foodstuffs are exhibited in Table 28. Notations regarding the separate commodities are as follows:

GRAINS AND THEIR DERIVATIVE PRODUCTS

49. Macaroni.—This item includes besides macaroni, the other alimentary paste products, spaghetti, vermicelli and spaghetti and the like. The analytical figures used were the averages of the analyses of macaroni, vermicelli and spaghetti, as given by Atwater and Bryant.

50. Rice.—This item includes the cleaned and rough (uncleaned) whole rice imported from all foreign countries and from our insular possessions, especially Hawaii. The uncleaned rice imports have been converted to a cleaned basis, before calculating the nutrients, so that the one item includes both cleaned and rough as cleaned.

51. Rice Flour.—This item includes rice flour, meal and broken rice. This agglomerate was assumed to have the same nutritive values as whole cleaned rice. A deduction will be made farther on for fodder and non-food uses of this item.

52. Wheat.—The nutrients in the flour from all the wheat imported were calculated, making allowance for a different rate of extraction in 1917-18, as in the case of our domestic production. Deductions will be made later.

53. Wheat Flour.—Total nutrients calculated.

VEGETABLES

54. Beans and Lentils.—The nutritional factors for this item were obtained by averaging Atwater and Bryant's factors for dried beans, dried lima beans and lentils.

55. Onions.—Nutrients in total imports calculated. Deductions for spoilage will be made later.

56. Peas, Dried.—Nutrients in total imports calculated.

57. Potatoes.—This item does not include sweet potatoes, the imports of which are too small to be separately listed by the Department of Commerce. The nutrients in the total imports were calculated. Deductions for spoilage will be made later.

SACCHARINE MATERIALS

58. Honey.—The Department of Commerce has given separate import figures on this item only for the fiscal years 1917-18 and 1916-17. The figures for the earlier years are estimates based on the assumption that the imports of this commodity were much smaller in the years when it was included in "all other articles."

59. Molasses.—Here the same nutrient factors as for domestic molasses were used, which, it will be recalled, left out the ostensible protein content on the ground that this was really nutritionally inert nitrogenous matter. Deductions from this item for industrial uses will be made later.

60. Beet Sugar.—Nutrients of total imports as refined sugar calculated.

61. Cane Sugar.—Cane sugar is imported into the United States in the form of raw sugar to the extent of all but a trifling amount. Before calculating nutrients the imports have been converted to terms of refined sugar (see p. 170 *supra* for the reason), on the assumption that 100 pounds of raw yields 93 pounds of refined.

62. Maple Sugar and Syrup.—The analytic factors used for this item were the averages of Atwater and Bryant's factors for maple sugar and maple syrup. Inasmuch as imports of these commodities were not separately reported until 1914-15 I have estimated the import of the three first years at the average of the four following years.

FRUITS

63. Bananas.—The import statistics are given in units of bunches. The average weight of a bunch has been taken here as 54 pounds and the Department of Commerce figures converted from bunches to pounds before calculating nutrients. A deduction of 10 per cent. is made for the stems before calculating nutrients. A further deduction for spoilage will be made later.

64. Currants.—Nutrients in total imports calculated.

65. Dates.

66. Figs.

67. Raisins.—In items 65, 66 and 67 the nutrients in the total imports have been calculated.

68. Olives.—Inasmuch as there is a great variation in the analysis of olives as reported by different authorities, and as import figures are given in gallons, and furthermore as both ripe and green

olives are imported and differ considerably in composition, it becomes a puzzling matter to decide upon proper nutrient factors for this item. After studying the matter it has been decided to take the Atwater and Bryant figure for green olives as purchased, as probably being as near to a fair average as one can get. A gallon of olives is taken to weigh 8.1 pounds.

69. Oranges.—On this item a departure has been made from the general rule of not considering imports stated in values only. Because of the desirability of getting a consumption figure for this fruit it was felt to be desirable to make some estimate of the imports in terms of poundage, using the value figures as the basis. This has been done with results which, if admittedly rough, are certainly nearer the truth than would be a complete omission of this import item.

VEGETABLE OILS AND NUTS

70. Almonds.

71. Filberts.

72. Peanuts.

73. Walnuts.

In items 70 to 73 inclusive the nutrients in the total imports have been calculated. Inasmuch as a portion of the imports in each of these cases is in the form of shelled nut meats, and the balance in the form of unshelled nuts, the nutrients have been separately calculated for the two moieties, and then the results combined to give the values here used.

74. Cocoanut, Shredded.—Only the shredded or manufactured portion of the cocoanut imports is taken here, because the edible oil from the rest of the cocoanut importation has been taken account of under production. The shredded cocoanut is used directly as human food.

75. Cream and Brazil Nuts.—Nutrients in the total imports were calculated.

76. Chinese Nut Oil.

77. Edible Olive Oil.

In items 76 and 77 the nutrients in the total importation have been calculated. No deductions are made here or later, as these oils are practically entirely used for food purposes.

78. Cocoanut Oil.

79. Cottonseed Oil.

In items 78 and 79 deductions for industrial uses will be made later. Here the nutrients of the total imports are taken.

80. Cacao, Crude.—This and the following item are included in the general group of oils and nuts, not because they have a completely logical status here, but because in a nutritional way they come nearer to this than to any other main group. The outstanding nutritional contribution of cacao and its products is fat.

The analytical figures for crude cacao were taken from Leach. In determining the protein factor the theobromine content was first subtracted from the total nitrogenous material. The factors here given are for the whole bean, nut and shell.

Here the entire nutrients in the imports are taken. Deductions will be made later for extracted cocoa butter industrially used.

81. Cocoa and Chocolate, Mfd.—This item does not include confectionery, but does include all other manufactured cocoa and chocolate. No deductions are made from this item, either here or later. For the analytical factors the average of Atwater and Bryant's figures for cocoa and for chocolate was used.

82. Cured Fish.—This item includes the following rubrics of the Department of Commerce Reports: "Cured cod, haddock, hake and pollock," "Cured herring" and "Cured mackerel." The analytical factors used are the averages of Atwater and Bryant's figures for (a) salt cod as purchased, (b) smoked haddock as purchased, (c) mackerel, salt, entrails removed, as purchased, (d) smoked herring as purchased, the salt cod being weighted twice to the others once, to allow for salt herring for which analyses are not available, and for the larger amount of cod in the composite figure.

83. Fresh Fish.—For this item the same nutrient factors were used as in the case of the item fish (No. 35) in Table 7. Since these figures were for edible portions only the same deduction for refuse, 48.184 per cent., has been made from the gross import figures as in the production statistics, before calculating the nutrients.

84. Crab Meat.—Nutrients in total importation calculated.

85. Lobsters.—This item includes both whole or fresh and canned lobsters.

The nutrients were calculated separately for the two sorts and the results combined.

The factors used in calculating nutrients in short tons from the commodity units given are exhibited in Table 27. The values got by these factors are changed to metric tons by multiplying by 0.9072.

* These are the factors for nutrients in flour from wheat for years 1911-17. For the year 1917-18 the factors are: Protein, 0.002531; fat, 0.000222; carbohydrate, 0.16672; calories, 0.073309.

The nutrient values of the gross imports are set forth in Table 28.

GROSS IMPORTS OF PRIMARY AND SECONDARY FOODS 101

TABLE 28.—SHOWING THE GROSS IMPORTS OF PRIMARY FOODS INTO THE UNITED STATES FROM 1911-12 TO 1917-18 INCLUSIVE

Reference No.	Commodity	Original units	1911-12

Average per year, war period....	5,761,183	122,786	194,991	4,060,997	18,971,729
Per cent. nutrient to total (whole period) and calories per lb.....		1.9	3.1	69.4	1456.9

The first noticeable feature of the summarized import data is the course of events in successive years. It is plain that throughout the seven years covered here there has been a steady increase in food imports. This increase has been relatively most marked in protein and fat. The precise character of these yearly changes is most clearly to be seen from Fig. 12.

The dominant position of sugar in our food imports is apparent. The carbohydrate line ascends steadily alongside the total line, but without showing the fluctuations of the latter. The fat and protein imports are insignificant as compared with the carbohydrate.

Comparing the prewar averages with those for the war years it is seen that the total gross primary food imports were 17.4 per cent. greater in the war period than prewar; the protein imports were 59.8 per cent. greater; the fat imports were 51.2 per cent. greater; the carbohydrate imports were 22.2 per cent. greater; and the calory content of the gross primary food imports was 25.3 per cent. greater in the war period. These are all notable increases. They indicate first the negligibly small effect of the German submarine campaign on our food imports, and second the fact that high prices in the United States in the war period greatly stimulated the imports of primary foodstuffs.

FIG. 12.—Showing the course of gross imports of primary food materials since 1911. Solid line denotes total primary food imports. Dash line, protein content of imported primary foods; dot line, fat content of imported primary foods; dash-dot line, carbohydrate content.

TABLE 30.—PERCENTAGES WHICH GROSS IMPORTS OF PRIMARY FOODS ARE OF DOMESTIC PRODUCTION OF PRIMARY FOODS

Year	Total imports	Protein	Fat	Carbohydrate	Calories
1911-12	15.0	4.4	12.2	23.7	20.3
1912-13	12.2	3.3	12.9	22.0	19.1
1913-14	14.7	4.3	16.2	23.5	20.7
1914-15	12.1	2.9	13.1	21.8	18.8
1915-16	12.2	3.2	17.4	20.9	18.6
1916-17	18.7	8.5	21.4	31.6	28.0
1917-18	17.0	9.7	27.2	28.5	26.4
Whole period.....	14.4	5.0	17.2	24.3	21.5
Prewar period.....	13.9	4.0	13.7	23.1	20.0
War period.....	14.8	5.6	19.7	25.1	22.5

It is a matter of great interest to see what proportion of our total primary food production the gross primary food imports form. In order to show this Table 30 has been prepared.

The data of Table 30 are shown graphically in Fig. 13.

The percentages of Table 30 are higher than would have been expected generally. We are accustomed to think of the United States as a food exporting country, which in a broad way it is.

FIG. 13.—Showing the percentages which total primary food imports are of total domestic production of primary foods. Solid line, total imports and total productions; dash line, protein; dot line, fat; dash-dot line, carbohydrate.

But this does not mean that it imports only insignificant quantities of food materials. Taking the three year prewar period the gross primary food imports were in total 13.9 per cent. of the total domestic production of primary foods. Or put in another way, of the total normal primary human food resources of the country, from which must come domestic consumption and export, about one pound was imported for every seven produced here. Substantially the same thing was true of fat in primary foods.

In the case of protein the prewar average gross primary imports were just 4 per cent. of our domestic production of protein in primary foods. The carbohydrate percentage is 23. This means that in the total carbohydrate resources of the country in the form of human foods approximately one pound was imported, for every four pounds domestically produced. These percentages greatly increased in the war period, as the last line of the table shows. In 1917-18, chiefly because of the falling off in sugar imports, the percentages for gross total, carbohydrate and calories fell off slightly. The protein and fat percentages were, however, higher.

Another matter of considerable interest is the weighted average analysis, as given in the last line of Table 29, of imported primary foods as compared with domestically produced primary foods. By comparing these figures with those given in Table 8 (Chapter III) it is seen that the imported foods contain less than half as much protein as the domestically produced. They are, however, richer in fat and carbohydrate, especially the latter. This of course arises from the tremendous relative weight of sugar in our primary food imports. If one were to consider the other primary food imports alone, leaving out the sugars, it would be found, as would be expected *a priori*, that the imports are much richer in protein and fat than the domestic production of the same food. Overseas trade in food naturally tends toward concentrated forms of nutriment.

We will now turn to a consideration of the gross imports of secondary human foods. The basic data are shown in Table 32. The conversion factors are given in Table 31. The data came from the reports of the Bureau of Foreign and Domestic Commerce, of the Department of Commerce. The general plan followed has been as in the case of primary food imports. No deductions are made at this point. Whatever deduction may be necessary will be made in connection with the consumption tables in a later chapter. "As purchased" analyses, which allow for inedible refuse as explained earlier (cf. p. 33 *supra*), are used throughout.

MEATS AND DERIVATIVE PRODUCTS

86. Beef and Veal.—These meats are given as one item in the import statistics of the Department of Commerce, and it is therefore impossible to separate them here. It is probable, however, that the veal constitutes only a very small fraction of the total under this rubric. Accordingly we have felt justified in using factors for

beef in calculating the nutrients. The same factors were used as for the item Beef in Chapter IV. (Reference No. 36.)

87. Mutton and Lamb.—Here again the factors for mutton (Reference No. 42) were used in calculating the nutrients, on the assumption that the great bulk of the imports fell into that category, and because of the impossibility of separating the imports.

88. Fresh Pork.—Here a different set of factors was used for calculating nutrients than in the case of domestic production, for the reason that in the production figures lard was included with the fresh pork. In the imports this would not be the case. As a matter of fact, a study of imported and exported meats indicated that the fairest factors to use in calculating nutrients for these items would be Atwater and Bryant's figures for medium fat loins. Accordingly that plan has been adopted for the imports.

89. Bacon and Hams.—The factors used for calculating nutrients were derived by first taking an unweighted average of Atwater and Bryant's figures for "Ham, smoked, all analyses" and "Shoulders, smoked, all analyses," and then taking an average of these figures and "Bacon, smoked, all analyses." This assumes an equal representation of bacon, hams and shoulders in the imports. This may or may not be correct, but even if it is not, any weighting to allow for difference in the import of the three commodities, would practically make very little difference in the final factors. This must clearly be so because of the general similarity of the analyses of these products.

90. Bologna Sausage.—Analytical figures were taken from Atwater and Bryant.

91. Oleo Stearin.—This material is taken as 100 per cent. fat.

POULTRY AND EGGS

92. Eggs, Whole.—The same analytical factors are used as in production statistics. (Reference No. 47.)

93. Eggs, Dried, Frozen, etc.—Here we are dealing with a group of egg products largely used by manufacturing bakers, etc. It being impossible to get any absolutely exact analytical figures for such a mixture the Atwater and Bryant factors for the edible portion only of fresh eggs have been used. This is as close an approximation as it seems possible to make. It would be rather seriously inaccurate if dried eggs formed any considerable proportion of the total, but we understand that such is not the case.

DAIRY PRODUCTS

94. Butter.—In the import statistics of the Department of Commerce butter substitutes are included with butter. No allowance can be made for this in the nutrient factors because of lack of data. Consequently we have used Atwater and Bryant's figures for butter.

95. Cheese.—This item in the imports includes "cheese and substitutes for." The "substitutes" must, however, be a very small fraction of the total. We have used Atwater and Bryant's figures for "cheese, full cream, as purchased" in calculating nutrient factors.

96. Cream.—Nutrient factors calculated from Atwater and Bryant's "Cream as purchased," analysis.

97. Milk.—This import item is given in the reports of the Department of Commerce only in terms of money value, and includes both fresh and condensed milk. The figures set down in Table 32 under this item are estimates of the whole fresh milk equivalent of this importation. Estimating the matter in this way gets over some difficulties in calculating nutrient values and probably leads to a more accurate final result than could be reached by attempting to deal with the condensed milk fraction of the total import separately.

Average per year, prewar	79,545	12,121	19,555	1,244	236,805
Average per year, war period.....	112,335	11,955	16,423	2,645	212,769
Per cent. nutrients to total (whole period) and calories per lb.....	12.2	18.1	2.1	102.9

The first thing which strikes one in connection with this table is that secondary food imports are of extremely little significance in the nutrition of the nation. In terms of gross commodity the secondary food imports in the whole period of seven years here covered were only 0.19 per cent. of the domestic production of secondary foods. Comparing in the same way the total of Table 32 with those of Table 12 (Chapter IV) for productions of secondary foods, we find the imported protein in 0.60 per cent. of domestic production; while for carbohydrate and calories the percentages are respectively 0.22 and 0.39. From these figures it is evident enough that the whole secondary food importation into the United States might be cut off absolutely, and from a nutritional point of view the population would never know that anything had happened. The contrast between the primary and the secondary foods in respect to their importation is striking. It would make a great difference

in the nutritional welfare of this country if our primary food imports for any reason stopped.

The secondary food imports are so small and unimportant in relation to the total that no special significance attaches to the yearly fluctuations in the amount of such imports. In general these imports increased to 1914-15, then fell off greatly in the next two years and revived a little last year.

A noteworthy feature of the secondary food imports is the very different weighted average composition which they show in comparison with the domestic production of the same class of food-stuffs. Such a comparison is afforded by the last lines of Tables 33 and 12 (Chapter IV). The protein content of the imported secondary foods is about 3 times higher than that of the domestic production and the fat and calory contents are each about twice as high. The difference seems largely traceable to the fact that all the nutrients of milk appear in the imports, while deductions were properly made in the domestic production of dairy products, and to the different relative contributions of the several commodities to the totals in the two cases.

CHAPTER VII

GROSS EXPORTS OF PRIMARY AND SECONDARY FOODS

(Commodity Reference Nos. 98-151)

We come now to the consideration of the last element necessary to a calculation of consumption, namely exports. The United States is, broadly speaking, a great food exporting nation. This phase of the general problem of making a nutritional balance sheet has, on this account, especial interest for us.

The general plan in dealing with exports will be the same as that of the earlier chapters, with some differences arising out of the form in which the basic statistics are available in the reports of the Department of Commerce. The export statistics of the United States in the strict sense of the word, are reported in two categories, namely; first, exports of domestic merchandise, meaning materials which either originate in this country or have been so manipulated as to enhance their value by processes of manufacture; and, second, exports of foreign merchandise, meaning the export of previously imported materials. There is still a third class of shipments out of the United States, namely those to our non-contiguous possessions, Hawaii, Porto Rico and Alaska. These latter shipments are not exports in a commercial or economic sense, but so far as the present study is concerned they are. In arriving at a balance sheet of the food in the United States it makes no difference whether wheat flour went to Hawaii or to China. In either case it left the continental area of the United States and was not available for consumption within that area. The foods shipped to us from these non-contiguous areas have been taken account of in imports and production. It is clear therefore that the outgo in the same directions must be set down on the other side of the ledger. Consequently three basic "export" tables are required in order to arrive at a final net export result: viz. Domestic Exports, Foreign Exports, and Shipments to Non-contiguous Possessions.¹ In

¹ It should perhaps be explained that the shipments in both directions between the United States and the Philippine Islands are included in the regular import and export statistics. In other words, these islands are regarded, in this sense, as a foreign country.

order not to encumber the text with too many and too detailed tables, it has been decided to present in this chapter only the following export tables:

1. Gross domestic exports of primary human foods to foreign countries and insular possessions.

2. Gross domestic exports of secondary human foods to foreign countries and insular possessions.

(1 and 2 comprise exports of human foodstuffs *produced* in the United States.)

To arrive at these final tables it was necessary to work out in addition detailed tables of (a) domestic exports to foreign countries, (b) domestic exports to insular possessions, (c) re-exports of imported foreign primary human foodstuffs, (d) re-exports of imported foreign secondary human foodstuffs. For the reasons above stated it seems unnecessary, however, to include all this detail here.

There is one further point in connection with the method of handling the export statistics here which needs careful discussion and explanation, because it is the point on which there is likely to be most difference of opinion and criticism. It will be noted in the export tables in this chapter that of the five great cereals, wheat, corn, oats, barley and rye, wheat is the only one included in the tables. In case of all the others only the derivative products appear and not the whole grain. Thus for corn, only the cornmeal export appears. The export of corn, as grain, is accounted for among the exports of "Primary feeds and fodders, including raw grains." The same is true of oats, rye and barley.

The first mental reaction of everyone at this point will be to say that surely the rye which is exported is used but slightly, if at all, as feed for animals. Of course it is not; so far there is no difference of opinion. But the first concern of this whole study is the most accurate determination possible of the *domestic* consumption of human food in the United States. We are not, here and now, primarily concerned with what happens to our food exports after they reach their destination. In determining human food consumption in this country we start with certain known general principles, of which the first is that, broadly speaking, no one of the five grains, wheat, corn, oats, barley and rye, is consumed as human food in the United States, at least in any appreciable quantity, until *after* it has passed through a manufacturing process such as grinding, cracking, rolling, etc. This being so, the amount used

in human consumption can be most accurately determined if we get statistics of the amount of the derived product, flour, meal, etc., actually produced by the mills of the country. This has been done in Table 7. The balance of the crop of each of the grains which remains after the manufacture of the derivative human food products is used up in one or another of three ways: either as food for animals, or as export, or for industrial, non-food purposes.

Since for reasons of accuracy, as above stated, the derivative products of the grains are alone considered on the *production* side of the human food ledger, it is clear that it would be unfair to balance against these the exports of the whole grains. This would give an erroneous result in two directions. First, and most important, it would make the domestic consumption appear smaller than it really is; and second it would imply that all of the raw grain exported goes to human food uses, which is only in degree less erroneous than to say that all of the export goes to animal feeding. The method here used of charging exports of derivative cereal products only against production, in balancing the *human* food ledger, gives accurate results as to domestic consumption, which is our primary problem. At the end of the analysis it also gives accurate results as to total amount of nutrients shipped abroad, because all of the raw grain imports and exports are accounted for in the tables dealing with the class of materials here grouped together under the rubric "Primary feeds and fodders, including raw grains." Wheat is the only grain differently treated, and in that case the total exports, as well as total imports, have been included in the human food tables because so very large a fraction of the crop goes to human food. It was simpler and just as accurate in such cases to deduct proper amounts for uses other than as human food. The corn crop presents exactly the opposite situation. Only a small fraction of it is consumed directly by human beings.

With this explanation it is hoped that the reader will be willing, for the sake of accuracy in the determination of our domestic consumption of food by human beings, to forego any reference value which would attach to having data as to exports and imports of the whole grains available here.

In Table 35 are given the total domestic exports of primary foods to all destinations, both foreign and U. S. insular, grouped as in former tables. Special explanations of the method of arriving at the figures are not necessary for many of the items. The nutrient

conversion factors used are the same as those which have been used in the earlier tables and the commodity statistics are taken without change from the reports of the Department of Commerce. In general no deductions for non-food uses, losses, spoilage, etc., are made on export figures, for the simple reason that the whole amount as stated leaves our shores, and we are not now concerned with what happens to it afterward. There are some commodities which have not appeared before, and for these special explanations follow.

GRAINS AND THEIR DERIVATIVE PRODUCTS

98. Bread and Biscuit.—For the calculation of nutrients of this item the weighted averages of all analyses of “crackers” as given by Atwater and Bryant were used. This includes Boston crackers, butter crackers, cream crackers, egg crackers, flat bread, graham crackers, miscellaneous crackers, oatmeal crackers, oyster crackers, pilot bread, pretzels, saltines, soda crackers and water crackers.

101. Rice.—The figures are for cleaned rice.

103. Wheat.—Nutrients in flour which would be produced from the stated amount of wheat were calculated, allowing as before for higher milling extraction in 1917–18. In other words, the figures represent what would have been the nutritive value of the exported wheat to the American people had it stayed here.

VEGETABLES

105. Beans and Dried Peas.—The factors for calculating nutrients were obtained by averaging Atwater and Bryant’s analyses of dried beans, dried lima beans and dried peas.

SACCHARINE MATERIALS

There is a small export of confectionery from the United States which is not reported except in money values. It is nutritionally so insignificant an item that it is not worth while to attempt to estimate poundage from the values given.

109. Grape Sugar.—The carbohydrate content is taken at 91 per cent. in calculating nutrient values.

113. Syrup.—This item does not include maple syrup. It is made up of the various sorts of mixed cane and corn syrups. In calculating nutrients on this item, an average carbohydrate content of 85 per cent. has been assumed.

114. Refined Sugar.—In the export statistics this item includes maple sugar. The proportionate amount of the latter in the total, however, is so very inconsiderable that no attention has been paid to its presence in calculating nutrients. In other words a carbohydrate content of 100 per cent. is used for this item.

FRUITS

118. Peaches, Dried.—Atwater and Bryant give no analysis of dried peaches. As a sufficiently close approximation the analysis of dried apricots has been used in calculating the conversion factors for dried peaches. These two fruits in the fresh state are very nearly alike in composition, and must also be so in the dried state.

FISH

127. Fresh Fish.—This item is the same as the "Fish, fresh, except salmon" export item of the Department of Commerce Reports. In dealing analytically with this rubric a different procedure has been followed than in the case of the production and imports. In both those cases it will be recalled that before calculating nutrients the inedible refuse was deducted. In the case of exports the following average of Atwater and Bryant's fresh fish "as purchased" analyses is used to get the conversion factors, and these are applied to the total poundage exported.

Protein.....	10.0 per cent.
Fat.....	2.8 per cent.
Calories.....	304 per pound

128. Cured Fish.—This includes the total exports of dried, smoked, and cured fish which are separately reported by the Department of Commerce under three heads, viz., (a) "Dried, smoked or cured cod, haddock, hake and pollack," (b) "Dried, smoked or cured herring," and (c) "Fish, dried, smoked or cured, all others." The same analytical factors were used as for the corresponding import item in Chapter VI.

129. Pickled Fish.—This is the "Fish, pickled, except salmon" item of the Commerce Reports. The same analytical factors were used as for item 127.

The conversion factors for such items as have not been given in previous chapters are presented in Table 34.

TABLE 34.—FACTORS BY WHICH AMOUNTS, IN ORIGINAL UNITS, OF DOMESTIC EXPORTS OF PRIMARY FOODS ARE TO BE MULTIPLIED TO GET SHORT TONS OF NUTRIENTS

Reference No.	Commodity	Original specified units of measure	To short tons of protein	To short tons of fat	To short tons of carbohydrate	To millions of calories

* In the total domestic exports of the year 1917-18 are included the shipments to the American Expeditionary Forces abroad, as well as shipments to the Commission for Relief in Belgium and American Red Cross.

The next point for consideration is the export of secondary foods. No summary or discussion of the gross domestic exports of primary foods will be made at this point for the reason that such discussion may better be deferred until some further data have been presented. The gross domestic exports of secondary human food materials appear in Table 37. There are certain items in the table which need explanation, but no space will be taken to discuss items which have simply received routine treatment, namely export statistics taken from Commerce Reports, and conversion factors based upon Atwater and Bryant's analyses of the same product, or the use of the same conversion factors as in earlier chapters for the same products.

MEATS AND DERIVATIVE PRODUCTS

132. Canned Beef.—The analytic values used to obtain conversion factors were those for canned corned beef, as given by Atwater and Bryant. The product is fairly representative of all the canned beef products in its composition.

133. Pickled Beef.—The analysis used was that of "salted mess beef" as given by Atwater and Bryant.

134. Fresh Pork.—The same factors were used as in Chapter VI for the imports of the same commodity.

135. Pickled Pork.—To obtain conversion factors an average was taken of the analyses of "Dry-salted bellies," "Salt pork, clear fat," and "Salt pork, lean ends" as given in Atwater and Bryant.

136. Canned Pork.—The analysis of canned boar's head was used, as being probably most nearly representative of the run of export canned pork.

138. Hams and Shoulders.—Average analyses of hams and shoulders were used.

139–141. Lard, Neutral Lard and Lard Compounds.—All these products were taken as 100 per cent. fat.

142. Sausage, Canned.—This item includes "canned sausage" and "all other sausage" of the domestic export list, and "sausage" of the insular list. The average was taken of all analyses of canned sausage as given in Atwater and Bryant. *Sausage, all other.* The average was taken of all analyses of fresh sausage as given in Atwater and Bryant.

143. Mutton.—This export item is exclusive of canned mutton. The same analysis was used as for mutton and lamb in Chapter IV.

144-146.—Stearin from Animal Fats, Tallow and Oleo Oil. These products were taken as 100 per cent. fat.

151. Milk, Condensed and Evaporated.—For the conversion factors an average was taken of Atwater and Bryant's figures for condensed, sweetened milk and evaporated, unsweetened milk.

The conversion factors for such products as have not previously appeared are given in Table 36.

TABLE 36.—FACTORS BY WHICH AMOUNTS, IN ORIGINAL UNITS, OF DOMESTIC EXPORTS OF SECONDARY FOODS ARE TO BE MULTIPLIED TO GET SHORT TONS OF NUTRIENTS

Reference No.	Commodity	Original units	To short tons of protein	To short tons of fat	To short tons of carbohydrate	To millions of calories
132	Canned beef.....	lb.	0.000131	0.000093	0	0.001280
133	Pickled beef.....	lb.	0.000056	0.000199	0	0.001890

138	Hams and shoulders	lb.	0.000067	0.000165	0	0.001644
139	Lard*.....	lb.	0	0.000500	0	0.004220
142	{ Canned sausage...	lb.	0.000082	0.000138	0.000001	0.001475
	{ Sausage, all other..	lb.	0.000114	0.000159	0.000003	0.001775
151	Milk, condensed and evaporated..	lb.	0.000046	0.000044	0.000163	0.001150

* The same conversion factors apply to neutral lard, lard compounds and substitutes, stearin from animal fat, oleo oil and tallow.

In Table 37 appear the detailed figures for gross domestic exports of secondary human food materials.

There is only one point regarding the shipments of food to our insular possessions which calls for special comment. It is this: if one examines carefully into the matter it will be found that there was a general tendency for the shipments of human food to Porto Rico and Hawaii to increase beginning with the year 1914-15, and continuing until 1917-18. Or, in other words, the export of food-stuffs to these territories showed the same reaction to war conditions as did exports to foreign countries. That this should have been the fact seems ridiculous, but it is a fact. It is difficult to conceive that the onset of a war in Europe in August, 1914 should have forthwith enhanced the need of the inhabitants of Hawaii and Porto Rico for imported food. The true explanation of this curious result is

TABLE 37.—TOTAL GROSS DOMESTIC EXPORTS OF SECONDARY HUMAN FOODS TO FOREIGN COUNTRIES AND INSULAR POSSESSIONS, FROM 1911-12 TO 1917-18

** In the total domestic exports of the year 1917-18 are included the shipments to the American Expeditionary Forces abroad, as well as shipments to the Commission for Relief in Belgium and American Red Cross.

probably to be found in the generally more sprightly selling activity, following the war's beginning, by firms doing an export business in this country. Generally people nowadays buy not what they need or want but what somebody succeeds in selling them. Having one's selling hand in, through practice on the foreigner who really had enhanced needs for imported foods as soon as the war was under way, it is easily conceivable that our insular brothers have been oversold.

With Tables 35 and 37 in hand we may proceed to an examination of the course of the export movement of human foods produced in the United States during recent years. A summary table which makes such study possible is given as Table 38.

TABLE 38.—SUMMARY OF GROSS EXPORTS OF PRIMARY FOODS
(Metric Tons)

Year	Total of all primary food ex- ports as commodity	Protein in primary food exports	Fat in primary food exports	Carbohy- drate in primary food exports	Calories (millions) in primary food exports
1911-12	2,764,822	208,248	212,783	1,620,606	9,479,617

Table 38 brings out clearly the profound change wrought in our export trade in primary human foodstuffs by the war. In 1914-15, the first year of the war, our gross exports of the commodities here under consideration more than doubled in comparison with the previous year. Since 1914-15 the gross total exports of

primary foods from this country have steadily fallen, year by year, until in 1917-18 the figure was back nearly to the prewar average, and actually smaller than the exports of the same group of commodities in 1912-13. A study of Table 35 shows that this decline since the first year of the war is almost entirely accounted for in the first group of commodities, namely the grains and their derivative products. To be still more specific it is in the export of wheat and its products that the great change has been. In 1914-15 we exported 8,556,274 metric tons of wheat and wheat products (flour, bread and biscuit). Against this the highest previous export was in 1913-14, with a total gross export of the same products of 3,619,382 metric tons, or less than half as much. It is obvious *a priori* that the export pace for wheat set in 1914-15 could not possibly be maintained, since in that year the total was swelled enormously by drawing on stored reserves, which high prices brought to light. Reserves, invisible supplies and the like can be drawn on to the point of exhaustion just once. Thereafter exports must come each year out of the surplus of that year's crop over domestic needs. In just such manner did events follow in the case of wheat and its products. After the banner export year of 1914-15 the amount sent away from our shores was smaller each year, reaching in 1917-18 a total (again for the same three products, wheat, wheat flour, bread and biscuit) of 3,008,707 metric tons. To be sure almost all of this went in 1917-18 to the Allies, which in 1914-15 was very far indeed from being the case. We have no occasion, in short, to reproach ourselves with having failed to do our just part in feeding the Allies. The decline in wheat exports since 1914-15 merely means that in each succeeding year since then the total amount of invisible wheat in reserve in this country, which the glitter of foreign gold would alone bring forth, was getting nearer and nearer the vanishing point. Before the end of 1916-17 it was all gone. The wheat exports of 1917-18 came out of, first a small exportable surplus from the crop of the same year, and to a much larger degree from the savings resulting from conservation, guided and directed by the Food Administration, but actually accomplished by the housewives of America.

The course of events in the successive years is shown graphically in Fig. 14, for the total exports and the individual nutrients.

The next point of interest to which attention may be turned is the relation of gross exports to production. Table 39 gives the facts for primary human foods. For each year and each nutrient com-

pound, there is stated in this table the percentage which the total gross exports form of the total domestic production.

FIG. 14.—Showing the course of gross exports of primary food materials since 1911. Solid line denotes total primary food exports. Dash line, protein content; dot line, fat content; dash-dot line, carbohydrate content.

TABLE 39.—SHOWING THE PERCENTAGES OF THE TOTAL PRODUCTION OF PRIMARY HUMAN FOODS SENT AWAY FROM THE UNITED STATES AS GROSS EXPORTS

Year	Total primary foods	Protein	Fat	Carbohydrate	Calories
1911-12	8.6	12.1	22.5	12.4	13.6
1912-13	11.8	17.9	20.4	17.0	17.5
1913-14	12.3	17.8	14.0	16.7	16.5
1914-15	23.1	34.2	21.0	32.7	31.5
1915-16	17.7	23.3	20.4	25.2	24.6
1916-17	20.5	29.5	14.6	29.9	28.0
1917-18	12.1	20.8	10.7	19.9	18.9
Total 7 years.....	15.4	22.6	17.7	22.4	21.9
Three prewar years..	11.0	16.1	19.0	15.5	16.0
War period.....	18.4	26.9	16.7	27.0	25.8

The results of the table are very striking. It is seen clearly how enormously our exports of primary human foods increased at the beginning of the war, in relation to production, in respect of all nutrients except fat. In the first year the ratio of exports to production about doubled for the total protein and carbohydrate. In the fat content of primary foods the ratio increased from the 1913-14 level to about what it was in 1911-12. In all cases the ratio fell off in 1915-16, because of the large production of that year, only to advance again in 1916-17. The latter year marked what is to be regarded as the most serious over-export in relation to production of any year of the war.

The situation in regard to the exports of fat in the form of primary foods, which includes all the vegetable fats used as human food, is interesting. In spite of the world shortage in fats the exports of this nutrient fell off markedly from the prewar average during the war period. As will presently appear, this was compensated for in the export of animal fats, but there is no apparent reason for the decline in the export-production ratio shown in the fat column of Table 39.

In 1917-18, our first year in the war, the export-production ratio fell back nearly to the prewar normal. This is unquestionably a healthy state of affairs at the beginning of a food exporting nation's participation in a great war. It means that we start off from an approximately normal base. If the exigencies of the occasion should demand it, a nation could later over-export in relation to production, just as we did in 1914-15. But at the end of 1917-18 we were clearly insured against any difficulty as to domestic needs because we were holding about a normal proportion of our food production in this country. It must again be emphasized, lest a wrong conclusion be drawn, that in 1917-18 practically our total food exports went to the Allies, instead of being distributed among many countries as in the prewar years. In other words, the decline of the export-production ratio in 1917-18 does not at all mean that we did not do our just part in feeding the Allies that year.

Another point which needs attention is the change in the nutrient concentration of our primary food exports in the war years as compared with prewar conditions. This matter will be more directly elucidated in a later table but the general drift of affairs is plain enough here. Comparing prewar and war averages it is seen that while the ratio of total primary food exports to production was

7.4 points higher in the war years than prewar, the protein export-production ratio advanced 10.8 points, the carbohydrate ratio 11.5 points, and the calorie ratio 9.8 points. Plainly more concentrated forms of primary foods were exported during the war period than in prewar years. This is of course as it should be. The fat content as before forms an exception. The export-production ratio for this nutrient was 2.3 points *lower* on the average in the war years than in the prewar years.

The general relations of the export-production ratio for primary human foods are shown graphically in Fig. 15 on a percentage basis.

FIG. 15.—Showing the percentage changes during the successive years in the ratio between gross exports and production of nutrients in the United States in the form of primary human foods.

It is seen that with the single exception of fat the export-production ratio was above the prewar average in each year of the war, by amounts varying from as low as 10 per cent. to as high as 112 per cent. This diagram raises an interesting question. How long could the country continue exporting food at a higher ratio to production than the normal average? It seems fairly clear from the 1917-18 figures that we had then about reached the end of such

exportations, and must drop back to the normal export-production ratio. In the earlier years of the war there were large invisible reserves particularly of the grains which could be drawn on to increase the ratio. As already pointed out these had disappeared by 1917. It is certain that the 1917-18 bars would have been below the line instead of above it, had it not been for the Food Administration's conservation campaign.

We may next turn to a further consideration of the exports of secondary foods. Table 37 gives the combined gross exports of these foods to foreign countries and to insular possessions. The results of Table 37 are summarized by years in Table 40. This enables a direct examination of the course of the secondary food exports in successive years.

TABLE 40.—SUMMARY OF GROSS EXPORTS OF SECONDARY FOODS
(Metric Tons)

Year	Total of all secondary food ex- ports as commodity	Protein in secondary food exports	Fat in secondary food exports	Carbohy- drate in secondary food exports	Calories (millions) in secondary food exports
1911-12	670,713	32,843	509,521	3,906	4,892,666
1912-13	602,343	27,821	464,651	3,236	4,451,617
1913-14	557,766	26,310	426,671	3,184	4,091,843
1914-15	796,543	63,226	504,728	6,956	4,986,398
1915-16	1,039,953	89,476	585,655	24,972	5,921,975
1916-17	1,101,550	97,841	598,251	40,072	6,136,091
1917-18	1,417,282	144,451	633,336	80,082	6,819,456
Total for 7 years.....	6,186,150	471,968	3,722,813	162,408	37,300,046
Average per year, whole period.....	883,736	67,424	531,830	23,201	5,328,578

Average per year, war period.....	1,088,832	98,748	580,493	38,021	5,965,980
Per cent. nutrients to total (and calories per lb.) 3 prewar years.....		4.8	76.5	0.56	3,329
Per cent. nutrients to total (and calories per lb.) war period.....		9.1	53.3	3.50	2,485
Per cent. nutrients to total (and calories per lb.) whole period.....		7.6	60.2	2.60	2,735

The course of the secondary food exports in successive years is shown graphically in Fig. 16, which is drawn on the same plan as Fig. 14.

It is at once apparent that the secondary food exports have followed a totally different course since 1911 to that shown in Fig.

FIG. 16.—Showing the course of gross exports of secondary food materials since 1911. Solid line denotes total secondary food exports; dash line, protein content; dot line, fat content; dash-dot line, carbohydrate content.

14 for the primary food exports. The overseas shipments of secondary food products were in process of steady decline before the war, reaching a minimum in 1913-14, the year immediately preceding the outbreak of hostilities. With that event began a marked rise in the curve, which has continued throughout the war, reaching a maximum (to date) in 1917-18. There is thus exhibited a beautiful compensatory behavior between primary and secondary

food exports. During the war period, as has been seen, the former decreased sharply, while the latter increased. The net combined result will be shown in a later table.

It is noteworthy that the export of fat in secondary foods during the war years has not kept pace with the total export of such foods. There is a distinct and increasing lag each year. In other words, our secondary food exports have been progressively less rich in fat during the war period. This has been due to the combined operation of two factors: first, an actual diminution in shipments of the more important pure animal fats such as lard; and, second, an increase in the proportion to the total secondary exports of the less fatty products, as for example meat and milk.

The change in the carbohydrate content of the secondary exports, which represents almost entirely the sugar in condensed milk, is most striking. The exports of condensed milk have increased so enormously in the past few years as to result in a total carbohydrate content of the secondary food exports more than 10 times as great in the war period as prevailed in prewar years. In 1917-18 we have the extraordinary result that in the total secondary food exports—animal products—there were something over one-half as many tons of carbohydrate as of protein.

The next point of interest is the relation of secondary food exports to the total domestic production of the same commodities. The necessary data are given in Table 41.

TABLE 41.—SHOWING THE PERCENTAGES OF THE TOTAL PRODUCTION OF SECONDARY HUMAN FOODS SENT AWAY FROM THE UNITED STATES AS GROSS EXPORTS

Year	Total secondary foods	Protein	Fat	Carbohydrate	Calories
1911-12	1.3	1.7	11.0	0.4	8.9
1912-13	1.2	1.4	10.3	0.4	8.3
1913-14	1.1	1.4	9.7	0.4	7.8
1914-15	1.5	3.2	10.5	0.8	8.8
1915-16	1.9	4.3	11.8	2.6	10.1
1916-17	2.0	4.6	11.9	4.1	10.3
1917-18	2.5	6.8	12.6	8.0	11.4
Total, 7 years.....	1.7	3.3	11.2	2.5	9.4
Three prewar years.	1.2	1.5	10.3	0.4	8.3
War period.....	2.0	4.7	11.7	4.0	10.2

From this table the following points appear:

1. There was in general a marked increase in the export-production ratio with the beginning of the war, in the case of secondary foods just as in the case of primary. This was true for all nutrients except fat.

FIG. 17.—Showing the percentage changes, during successive years, in the ratio between gross exports and the production of nutrients in the United States, in the form of secondary human foods.

2. By comparing Table 41 with Table 39 it is apparent that, even at the highest point, the export-production ratio is much smaller for secondary foods than for primary. In other words we export a much larger proportion of our production of primary foods than we do of secondary. The actual comparisons for the average of the whole 7 year period are: For total food, 15.4 per cent. to 1.7 per cent.; for protein, 22.6 per cent. to 3.3 per cent.; for fat, 17.7 per cent. to 11.2 per cent.; for carbohydrate, 22.4 per cent. to 2.5 per cent.; for calories, 21.9 per cent. to 9.4 per cent.

3. The fat in secondary food exports shows the least relative change in the export-production ratio in the war period as compared with the prewar period, and carbohydrate shows the greatest relative change. This is clearly shown in Fig. 17, which is drawn on the same plan as Fig. 15 for primary foods.

It is evident from this diagram that the relative increases during the war period in the export-production ratio were, on the whole, much greater in the secondary than in the primary foods, though the ratios themselves were absolutely higher in the latter group. The changes in the export-production ratio for protein and carbohydrate in secondary foods were enormous.

It will be of interest next to combine the gross exports of primary and secondary foods in a grand total, in order that the general trend of all human food exports from this country during the war may be seen. This is done in Table 42, which combines into a single series of totals the data of Tables 38 and 40.

By comparing this table with Table 14 in Chapter V it is seen at once that the contribution of primary and secondary foods in the exports is very different from what it is in production. Whereas of the total human food produced 58 per cent. is of secondary origin, only 13 per cent. of the exported food is secondary. A considerably larger proportion of the exported fat is of primary origin than in the production. Of the total calories exported 77 per cent. are of primary origin, while of the total calories produced 59 per cent. are primary. In short, primary foods are exported in higher proportion to secondary than they are produced.

| The changes in human food exports as a result of the war are shown in total in Table 42. Taking the four war years as compared with the three prewar it is seen that the total food, protein and carbohydrate exports about doubled in the war period. The fat exports increased about one-sixth. The exported calories nearly doubled. These facts enable us to form a picture of the significance of our food exportation during the war. While our average annual food *exports* nearly doubled during the war period, the average annual food *production* in this country increased in the same period less than 10 per cent. But percentages on such different bases may be misleading. Figures 18 and 19 show graphically the true relation between production and export of human foods.

TABLE 42.—TOTAL GROSS EXPORTS OF HUMAN FOOD FROM THE UNITED STATES
(Metric Tons)

Year	Total of all human food exported	Per cent. from		Total exported protein	Per cent. from		Total exported fat	Per cent. from		Total exported carbohy- drate	Per cent. from		Total exported calories	Per cent. from

Fig. 18.—Diagram showing the relation between annual average production and annual average gross exportation of all human foods and their calory content, in prewar years and in the war period.

Fig. 19.—Diagram showing the relation between annual average production and annual average gross exportation of protein, fat and carbohydrate in human foods in prewar years and in the war period.

From these diagrams it is evident that the average annual excess of gross human food exports in the war period over prewar was not generally greater, and was in some cases distinctly smaller than the average annual excess in production in the war period as compared with the prewar. To make the comparison precise on this point, and also introduce the year 1917-18, Table 43 has been prepared.

TABLE 43.—COMPARING THE ABSOLUTE EXCESS IN AVERAGE ANNUAL EXPORTATION OF HUMAN FOODS WITH THE EXCESS IN PRODUCTION OF THE SAME FOODS IN THE WAR PERIOD AND THE PREWAR PERIOD

Item	Absolute excess in war period as compared with prewar period in average annual		Absolute excess in 1917-18 as compared with prewar average annual	
	Production	Gross exportation	Production	Gross exportation
Total human food (metric tons).....	8,033,858	3,826,678	7,460,379	1,369,843
Protein content (metric tons).....	395,512	344,161	233,921	214,233
Fat content (metric tons).....	490,390	100,985	605,498	97,695
Carbohydrate content (metric tons).....	1,855,113	2,162,064	541,494	807,927
Calories (millions).....	13,752,898	11,220,272	8,817,732	5,106,747

It is clear from this table that the excess of domestic production of human foods during the war period was *not* entirely exported, save in the case of carbohydrate. There has been, of course, a larger and a more prosperous domestic population during the war period than prewar, and this will account for some of the difference—probably for all of it and even more in the case of protein. But the broad fact is that while it is true that we doubled our exports of human food while production increased less than 10 per cent., and furthermore notably increased the export-production ratio, there nevertheless remained in the country more tons of human food (with the exception of carbohydrate) during the war period than did in the three years preceding the war. The case in 1917-18 was in some respects worse than for the whole war period and in some respects better. It was chiefly better in two respects: First, the concentration of nutrients of the exported human foods was high in 1917-18 (compare calories with total food in last two columns of Table 43); and, second, in that virtually all the exports in 1917-18 went to the Allies. The latter is the really outstanding feature of the case.

The relative concentration of nutrients in exported human foods is much greater than in the total production, as would be expected. The calory content of exported foods is rather more than double that of all foods domestically produced.

Figure 20 shows graphically the course of the export movements in the successive years.

FIG. 20.—Showing the course of total human food exports since 1911. Solid line denotes total human food exports. Dash line, protein content; dot line, fat content; dash-dot line, carbohydrate content.

From this diagram it is evident that the compensatory increase in secondary food exports during the war years was not sufficient in magnitude to offset the downward tendency of the primary food exports. The fat exports form a nearly horizontal line.

Consideration may next be given the question of the relative importance of the different human food commodities and groups of commodities in the exports. In approaching this matter it has seemed best to use averages for the prewar period (3 years) and the war period (4 years) rather than to take an average of the whole

seven years, as was done for production. The reason obviously is because the volume of the exports was so violently changed by the war, while the changes in production are only such as might happen at any time one had a succession of two or three good crop years.

Tables 44 to 47 give the group averages and percentages for the different nutrients, as well as the cumulated percentages.

TABLE 44.—GROSS EXPORTS OF PROTEIN IN ALL HUMAN FOODS, ARRANGED BY COMMODITY GROUPS, IN DESCENDING ORDER OF IMPORTANCE

Group	Annual average during prewar period			Annual average during war period		
	Total protein (metric tons)	Per cent. of total protein	Cumulated per cent.	Total protein (metric tons)	Per cent. of total protein	Cumulated per cent.

The overwhelming importance of the grains in furnishing protein in our human food exports is clear. This commodity group furnished 87 per cent. of the protein in the exports before the war, and 81 per cent. during the war period. The contribution to protein exports by the meats rose in the war period to 12 per cent., from the 7 per cent. which it had been before. In the prewar period dairy products had stood in the seventh place, contributing less than a half of our per cent. of the exported protein (in human foods). During the war period the dairy products rose to third place, furnishing nearly two and a half per cent. of the total exported protein. This is the most notable change in position in the table. The fruits and fish, low in nutrient concentration, dropped down in relative position in the table during the war years, as would have been expected.

TABLE 45.—GROSS EXPORTS OF FAT IN ALL HUMAN FOODS, ARRANGED BY COMMODITY GROUPS, IN DESCENDING ORDER OF IMPORTANCE

Group	Annual average during prewar period			Annual average during war period

Fish.....	0	0.000	100.000	0	0.000	100.000
Poultry and eggs.....	0	0.000	100.000	0	0.000	100.000
Totals.....	2,236,218	100.000	4,398,283	100.000

In the fat exports of human foods the oils and nuts, without changing their relative position, lost in percentage contribution to total, and the grains and dairy products gained, the latter notably. The meat group also gained, and is, of course, outstanding in its contribution to total fat exports. The three groups, meats, oils and nuts, and grains, together contribute 95 to 99 per cent. of our total fat exports in human foods.

In carbohydrate exports the grains, of course, come first. Their percentage contribution dropped somewhat, however, during the war period. The sugar made a notable gain in percentage contribution during the war, while the fruits fell off as would be expected.

TABLE 47.—CALORY CONTENT OF ALL EXPORTED HUMAN FOODS, ARRANGED BY COMMODITY GROUPS, IN DESCENDING ORDER OF IMPORTANCE

Group	Annual average during prewar period			Annual average during war period		
	Total (millions of) calories	Per cent. of total calories	Cumulated per cent.	Total (millions of) calories	Per cent. of total calories	Cumulated per cent.
Grains.....	9,468,253	57.18	57.18	17,780,773	64.01	64.01

Fish.....	64,389	0.39	99.57	266,453	0.96	99.54
Dairy products	55,176	0.33	99.90	105,550	0.38	99.92
Poultry and eggs.....	16,715	0.10	100.00	22,054	0.08	100.00
Totals.....	16,559,534	100.00	27,779,806	100.00	

Here in final summary it is seen that the grains and meats contribute together about 84 per cent. of the total energy value of the human food exports. They contributed this proportion before the war, and almost identically the same proportion since, what one group lost the other having gained. During the war dairy products moved up to fifth place, from eighth where it had been before.

Tables 48 to 51 give the relative nutritional importance of individual commodities in the total human food exportation. This is of considerable interest in comparison with the similar tables for production given in Chapter V and consumption in Chapter IX.

TABLE 48.—GROSS EXPORTS OF PROTEIN IN ALL HUMAN FOODS, ARRANGED BY COMMODITIES, IN DESCENDING ORDER OF IMPORTANCE

	Total.....	27,779,806	100.000	

Wheat and wheat flour stand at the head here as would be expected, from data already presented. Together they account for about 80 per cent. of the protein exported in human foods. There are many notable changes in the position of commodities in the war years as compared with prewar. Thus fresh beef moved up from twentieth to fifth place in relative importance. Fresh pork moved up from thirty-fourth place to sixteenth. Rye flour advanced from thirty-seventh to nineteenth place. Condensed milk, as has been seen already, made a notable advance in its export significance, changing from fifteenth place to the eighth.

Before the war five commodities, wheat, wheat flour, hams and shoulders, bacon and rice accounted for more than 90 per cent. of the protein exported in human foods. During the war period rice has been dropped from this list, and four other commodities have come in, namely, fresh beef, beans and dried peas, oatmeal and rolled oats, and condensed and evaporated milk. So that, during the war period eight commodities contributed 90 per cent. of the total exported protein.

Lard stands at the top of the list in both periods, but it contributed 10 per cent. less to the total fat exports in the war period than before. One observes in the case of the fat the same thing which was apparent in protein exports, namely that in the war period there was an increased scattering of exports of nutrients among different commodities. Thus in the present case, while in the prewar period 9 commodities contributed over 90 per cent. of the total fat exported in human foods, in the war period 13 commodities were required to get over the 90 per cent. mark. In both periods only two primary products were included in this 90 per cent. group, namely cottonseed oil and wheat (including flour in the war period). The most notable single commodity advance in percentage contribution to fat exports during the war is perhaps that of bacon, though it involves only a slight change in position in the table. But bacon which contributed 8 per cent. of the total exported fat in prewar times contributed 22 per cent. during the war period.

Of the total exported carbohydrate four or five commodities, wheat, flour, rice and syrup or refined sugar and glucose account for over 90 per cent. In the prewar period syrup was one of the five commodities necessary to make up 90 per cent., but was replaced during the war period by refined sugar. Also glucose came in the list before the war. Condensed milk moved up from nine-

FIG. 21.—Diagram showing the relative importance of different commodities in the gross exports of protein in human foods.

FIG. 22.—Diagram showing the relative importance of different commodities in the gross exports of fat in human foods.

teenth to ninth place, because of the tremendously increased exports and its high sugar content.

Table 51 well shows the readjustment and changes in human food exports brought about by the war. In both prewar and war periods 12 commodities contributed over 90 per cent. of the total caloric value of the exports. But only 8 out of the 12 commodities

FIG. 23.—Diagram showing the relative importance of different commodities in the gross exports of carbohydrate in human foods.

on the prewar 90 per cent. list appear in the war period 90 per cent. list. And only 7 out of the 12 commodities on the war 90 per cent. list appear in the prewar. Refined sugar advanced during the war period to third place in caloric contribution to the exports, whereas formerly it had been in the fourteenth place in the commodity list. Cornmeal and oatmeal, as well as, of course, condensed milk, became more important factors in the nutrient exports during the war. Fresh beef came forward from forty-first

position to fourteenth. But even then fresh beef contributed less than 1 per cent. to the total caloric value of the exported human foods. In general, foods of relatively high nutrient concentration moved up in the list during the war and those of relatively low nutrient concentration went down. This is, of course, an expected consequence of the shortage of tonnage.

FIG. 24.—Diagram showing the relative importance of different commodities in their contribution to the caloric content of exported human foods.

As a whole these tables bear out the point made when the similar production tables were under discussion, namely that the contribution of a relatively few food commodities to the total is so tremendous that a whole flock of really minor, though usually considered important, staple foods might be totally neglected without making any special difference in the net nutritional result. This fact is so evident that in the days of Paley it might well have been adduced as a special instance of the goodness of God to food administrators as a class.

The data of Tables 48 to 51 are shown graphically in Figs. 21 to 24.

It is evident from these diagrams that, in our exports of human food, wheat, wheat flour, lard, bacon, cottonseed oil, hams and shoulders, and refined sugar are the only items of special significance in a nutritional sense. All but a relatively small percentage of the total nutritional value of the human food exports is comprised in these commodities.

Before leaving the subject of exports, and concluding this chapter, it is necessary to recall to mind that the data regarding what are technically called "foreign exports," which are the re-exports of imported foods of foreign origin have not been presented. The amounts involved are not generally large, but in arriving at a final net export balance accurately it is essential to include these re-exports of imported articles. It does not seem necessary, however, to present the detailed figures here. In arriving at net exports and imports, given in the next chapter, the "foreign export" figures were used in attaining the final result.

CHAPTER VIII

NET IMPORTS AND NET EXPORTS OF PRIMARY AND SECONDARY HUMAN FOODS

It is now possible, by combining the data discussed in Chapters VI and VII to arrive at net figures on imports and exports. The first step in this process is to make net foreign import tables, which can be done by combining Tables 28 and 32 in Chapter VI, which exhibit the gross importation of primary and secondary human foods, with the tables prepared in connection with, but omitted from Chapter VII, which exhibit the re-exportation of these same imported foods. The balance, shown in Tables 53 and 55, gives the amount of imported foods remaining in this country for consumption therein.

In Chapter VI it was pointed out that in making the nutrient calculations on imports no deductions for loss, spoilage, etc., were there made, it being the intention to make such allowances on the final net import tables. This is done in Tables 53 and 55. In arriving at the amounts to be deducted it has been necessary simply to make the best percentage estimate possible, there being no exact statistics on the matter. Some of these estimates are certainly rough, but it must be remembered that because of the slight importance of imports in the total nutritional intake of this country, with the exception of sugar and rice, an estimate of a deduction for industrial use or spoilage may be very far out of the way without having any significance in the final consumption result. The United States is, in this regard, in a very different position from a nation dependent upon imports for the major portion of its food. Anyone who is critically interested may calculate for himself the effect of doubling or halving the percentage deductions of imports listed in Table 52 upon the final per capita consumption figures of Chapter IX. He will find that only an insignificant and inappreciable effect is produced.

TABLE 52.—PERCENTAGE DEDUCTIONS FROM NET FOREIGN IMPORTS FOR NON-FOOD USES, SPOILAGE, WASTE IN STORING, HANDLING, TRANSPORTATION, ETC.

Commodity	Percentage deduction	Remarks
Rice flour.....	50 per cent.	This item includes rice flour, meal and broken rice. None of the meal goes to human food. It is estimated to average half the total item. The broken rice used in brewing has been all allowed for in production figures, though some of the imports are so used. Here all the broken rice is therefore allowed to go in as human food.
Wheat.....	5 per cent.	For loss in storage and transportation. Some of the imports are used for seed, but all the nutrients in the seed used have been allowed for in production and so no deduction is made for this item here.
Onions.....	10 per cent.	For spoilage in storage and distribution.
Potatoes.....	10 per cent.	For spoilage in storage and distribution.
Molasses.....	60 per cent.	It appears that at least this proportion of imported molasses goes to other than human food uses.
Bananas.....	10 per cent.	For spoilage in distribution.
Oranges.....	5 per cent.	For spoilage in distribution.
Cocoanut oil...	100 per cent. 1911-12	For non-food industrial uses on the assumption that the distribution of the imported oil between food and non-food uses is the same as that of the domestically produced oil.
	100 per cent. 1912-13	
	99.5 per cent. 1913-14	
	97.5 per cent. 1914-15	
	98 per cent. 1915-16	
	99 per cent. 1916-17	
	87 per cent. 1917-18	Cf. preceding item.
Cottonseed oil..	5 per cent. 1911-12	
	6 per cent. 1912-13	
	6 per cent. 1913-14	
	5 per cent. 1914-15	
	9 per cent. 1915-16	
	7 per cent. 1916-17	To allow for cocoa butter not used as food.
	5 per cent. 1917-18	
Cacao, crude...	25 per cent. of fat content, 18 per cent. of calories.	

In Table 52 are listed the items on which deductions have been made, showing the amount in each case. These amounts are stated in percentages and are to be understood as percentages of the net imports deducted. For example, suppose in a particular year x bushels of wheat were imported and y bushels were re-exported. Then $(x - y)$ is the net import. According to Table 52 the deduction on wheat is 5 per cent. Then the final figure which appears in Table 53 for net wheat imports is $(x - y) - 0.05 (x - y)$. The same rule is applied in all the other cases. In the case of items not mentioned in Table 52, no deductions have been made.

The same percentage deductions are applied to each of the seven years, except in the case of cottonseed and cocoanut oils. Undoubtedly the true losses and industrial uses vary somewhat from year to year, but it is assumed that these variations are likely to be as often in excess as in defect of the percentages here used. In the case of the oils more definite figures can be arrived at, and hence are used.

The net primary food imports consumed in the country are shown in Table 53.

TABLE 53.—SHOWING NET FOREIGN IMPORTS OF PRIMARY FOODS CONSUMED
IN THE UNITED STATES, AFTER DEDUCTING RE-EXPORTS, NON-FOOD USES
AND LOSSES

Table 53 is summarized by years in Table 54.

TABLE 54.—SUMMARY OF IMPORTED PRIMARY FOOD CONSUMED IN THE UNITED STATES
(Metric Tons)

Year	Net imports in metric tons	Protein in metric tons	Fat in metric tons	Carbohy- drate in metric tons	Calories in millions
1911-12	4,434,301	69,119	85,405	2,972,380	13,266,202
1912-13	4,254,828	58,895	87,207	3,142,046	13,936,761
1913-14	4,734,580	78,320	109,697	3,336,372	15,022,582
1914-15	4,580,963	56,984	100,681	3,446,653	15,303,771
1915-16	4,808,763	69,747	113,580	3,663,195	16,363,152
1916-17	5,475,009	136,865	144,009	3,968,499	18,173,284
1917-18	5,349,100	166,976	154,521	3,791,210	17,667,171
Total, 7 years.....	33,637,544	636,906	795,100	24,320,355	109,732,923
Annual average, whole period.....	4,805,363	90,987	113,586	3,474,336	15,676,132
Annual average, 3 pre- war years.....	4,474,570	68,778	94,103	3,150,266	14,075,182
Annual average, war period.....	5,053,459	107,643	128,198	3,717,389	16,876,845
Per cent. nutrients to total (and calories per lb.), 3 prewar years.....		1.5	2.1	70.4	1426.8
Per cent. nutrients to total (and calories per lb.), war period.....		2.1	2.5	73.6	1514.9
Per cent. nutrients to total (and calories per lb.), whole period.....		1.9	2.4	72.3	1479.7

From this table it is evident that in general the amount of imported primary foods consumed in the United States has increased steadily since 1911-12. The energy content has gone up every year except the last. There are some fluctuations in the protein and fat curves but the general upward trend is unmistakable in all. In all cases the annual average for the war period is higher than in the prewar years.

The secondary food imports consumed in this country are exhibited in Table 55.

TABLE 55.—SHOWING NET FOREIGN IMPORTS OF SECONDARY FOODS CONSUMED IN THE UNITED STATES, AFTER DEDUCTING RE-EXPORTS

Commodity	1911-12

Per cent. nutrients to total (and calories per lb.), war period.....	10.5	14.7	1.6	845.8
Per cent. nutrients to total (and calories per lb.), whole period.....	12.2	18.3	1.6	1028.3

The same regular course of net imports consumed here is not observed in the case of secondary foods as was with the primary (cf. Table 54). The high points for net secondary food imports were in 1913-14 and 1914-15. The annual average net import rate was lower in the war period than prewar for protein, fat and calories. Further, the nutrient concentration of the net secondary food imports fell off greatly, on the average, in the war period. This is in marked contrast to the net primary food imports, where the concentration of nutrients on the average increased in the war period.

Tables 54 and 56 are combined in Table 57, which shows the net imports by years of all human foods.

TABLE 57.—SUMMARY OF IMPORTED HUMAN FOOD CONSUMED IN THE UNITED STATES
(Metric Tons)

Years	Net imports in metric tons	Protein in metric tons	Fat in metric tons	Carbohydrate in metric tons	Calories in millions
1911-12	4,466,370	75,099	96,397	2,973,140	13,396,029
1912-13	4,299,352	66,307	102,043	3,142,926	14,108,760

1917-18	5,437,854	173,290	165,162	3,794,145	17,804,073
Total, 7 years	34,295,617	717,223	915,375	24,330,820	111,224,700
Annual average, whole period	4,899,374	102,460	130,768	3,475,831	15,889,243
Annual average, 3 pre-war years	4,553,990	80,878	113,621	3,151,498	14,311,509
Annual average, war period	5,158,412	118,647	143,628	3,719,081	17,072,543
Per cent. nutrients to total (and calories per lb.), 3 prewar years		1.8	2.5	69.2	1425.5
Per cent. nutrients to total (and calories per lb.), war period		2.3	2.8	72.1	1520.2
Per cent. nutrients to total (and calories per lb.), whole period		2.1	2.7	70.9	1471.1

The data of Table 57 are shown graphically in Fig. 25. It is clear that the general tendency has been toward the consumption of more and more imported foods in this country during the period under investigation, but the course of events has not been entirely regular. This is shown in Fig. 25.

The preponderant effect of sugar in the net imports of food is clear. The carbohydrate line is the dominant one. About 70 per cent. of the weight of all the food brought into the United States for consumption is carbohydrate. Protein and fat form a very small part of the imported food.

The way is now cleared for the final net export and import table,

which is the last step necessary for the calculation of consumption. Table 58 gives the net balance sheet of the external movement of foodstuffs to and from this country. The figures in this table are the result of taking for each commodity the difference between the total gross exports, and the imports for consumption, and calling the balance minus when more goes out of the country than comes in, and plus when the case is the other way about. In other words,

FIG. 25.—Showing the course of net foreign imports of human foods (consumed in the United States) since 1911. Solid line denotes total net food imports; dash line, protein content; dot line, fat content; dash-dot line, carbohydrate content.

Table 58 gives the balances resulting from algebraically adding the total gross exports (—) of Tables 40 and 43 and the residual imports for consumption (+) of Tables 53 and 55. If the residual imports are larger than the gross exports the balance will be plus, and will be marked + in Table 58. If, on the other hand, the gross exports are larger than the residual imports the item will be marked minus. To get consumption it is necessary then only to add or subtract, according to the sign of the item, the figures of Table 58 to the corresponding production figures.

TABLE 58.—FINAL NET BALANCE OF EXPORTS (−) AND IMPORTS (+) OF HUMAN FOODSTUFFS FROM 1911 TO 1918

Table 58 includes both primary and secondary foods. Certain special items, such as flour, bread and biscuit, macaroni, etc., which have up to this point been handled separately in the import and export statistics, are here combined, in the interest of simplicity, and referred to the basic raw material, in this case wheat. This combination simplifies the table and at the same time leads up to a more accurate determination of consumption than would be possible if the attempt were made to handle the special items separately.

This table furnishes a great deal of information not hitherto available in readily comprehensible form. We commonly think of this country as a food exporting nation, but the matter when analyzed is not to be covered by any such simple offhand statement. There are very complex interrelationships of human food materials in their export and import movements.

In order to gain a comprehensive idea of the matter it will be well to start with a yearly summary of Table 58. This is given in Table 59.

TABLE 59.—SUMMARY OF NET IMPORTS AND EXPORTS OF HUMAN FOOD
(Metric Tons)

Years	Net exports (commodity)	Protein	Fat	Carbohy- drate	Calories (millions)
1911-12	+ 1,030,835	- 165,992	- 625,907	+ 1,348,628	- 976,254
1912-13	- 802,710	- 319,255	- 550,895	+ 592,360	- 4,007,552
1913-14	- 69,887	- 286,918	- 417,346	+ 804,851	- 1,760,267
1914-15	- 5,820,018	- 777,692	- 601,440	- 2,143,842	- 17,578,931
1915-16	- 4,070,250	- 617,210	- 647,206	- 1,164,165	- 13,331,623
1916-17	- 2,354,481	- 480,807	- 583,161	- 158,839	- 8,056,312
1917-18	- 433,233	- 379,209	- 577,537	+ 750,000	- 3,862,308
Totals, whole period	- 12,519,744	- 3,027,083	- 4,003,492	+ 28,943	- 49,573,247
Annual average, whole period.....	- 1,788,535	- 432,440	- 571,927	+ 4,135	- 7,081,892
Annual average, 3 prewar years.....	+ 52,746	- 257,388	- 531,383	+ 915,280	- 2,248,024
Annual average, war period.....	- 3,169,495	- 563,729	- 602,336	- 679,224	- 10,707,293

The data of Table 59 are shown graphically in Figs. 26 and 27. Figure 26 gives the net exports of human food commodities as such while Fig. 27 gives the nutrients.

FIG. 26.—Showing the net exports and imports of all human food commodities from 1911 to 1918.

FIG. 27.—Showing the protein (dash line), fat (dot line), and carbohydrate (dash-dot line) content of the net exports and imports of human foods in the United States, 1911 to 1918.

Taking all human foods together in this way, it appears that in 1911-12 we imported a greater total tonnage of food commodities than we exported. Each year since the export tonnage has been greater than the import, but in 1913-14 the departure from the line of balance was only very slight. In the first year of the war, 1914-15, the net export of human foods was over 5,000,000 metric tons—a stupendous amount. After that year the net export fell off rapidly year by year until in 1917-18 the net export line was nearly back to the zero balance line, and almost in the position that it was in the prewar period.

During the whole period this nation has had a net export balance of protein and fat in human foods. And, as Fig. 27 shows, the war has not greatly changed the horizontal course of the lines for these two nutrients. The case is very different with carbohydrate. The United States had a net import of carbohydrate before the war. Its enormous import of sugar was sufficient more than to offset all the carbohydrate in exported foods. With the outbreak of the war, however, and the enormous exports of breadstuffs and increased exports of sugar the carbohydrate balance swung very far down on the export side in 1914-15. Since then it has been swinging back again, until in 1917-18 the United States was once more in the prewar condition of having a net import of carbohydrate.

The story of the separate commodity groups is an interesting one. In the case of the grains used as human food and their derivative products we have had a net export balance throughout the period investigated. The only point of note is its amount, which increased enormously in the early years of the war.

The vegetables in general showed a net import balance in the prewar years. The scale turned the other way to a small export balance during the first two years of the war, and then in 1916-17 swung back the other way to a net import balance which increased (so far as nutrients are concerned) in 1917-18.

The sugars are always a net import balance commodity group. The amount runs nearly level, speaking in a broad way, year after year.

Fruits show a net import balance every year. The net import of bananas far overtops the net exports of most of the other fruit items.

Oils and nuts form a heterogeneous group. Nuts exhibit, of course, a net import balance throughout. Vegetable oils show

a diminishing net export balance to 1917-18 when it turns to an import balance. It must be remembered always that we are now speaking only of commodities used as human food. The course of the vegetable oils is so interesting that it seems worth while to show it graphically, as is done in Fig. 28.

FIG. 28.—Net exports and imports of vegetable oils used as human food since 1911-12.

Chocolate and cocoa, of course, exhibit always an import balance.

Fish show a small net import balance throughout.

Turning to the secondary foods a more consistent condition of net exportation is encountered. In the meat products the balance is always in this export direction, increasing steadily in amount during the war period. The same is true of poultry and eggs and oleomargarine.

The dairy products have exhibited an extreme change in their import-export movement in the period here covered. Before the war we showed a small but growing import balance of these products. With the onset of the war the balance went the other way and we have a steadily increasing net export. The facts are shown graphic-

ally in Fig. 29. The calory content is the figure plotted in this case.

What this diagram means is that before the war we added to our national nutritional resources by importing increasing amounts of dairy products. Since the war we have subtracted from our

FIG. 29.—Net exports and imports of dairy products since 1911-12, expressed in items of calories.

human food resources in this country by sending out ever increasing amounts of milk and its products.

It is of interest to compare the totals of Table 59 with those of Table 14 (Chapter V) which gives the total production of human food in the United States. Taking the whole seven years investigated as a unit it is seen that the net amount of human food (as commodity) subtracted as net exports from our national food resources was, in round figures, 12.5 million metric tons. In

the same period we produced 630.4 million metric tons of human food. In other words, our *net* loss or outgo of human foods as exports was *rather less than 2 per cent. of our total production of the same foods.*

Owing to the relatively high nutrient concentration of exported foods, a slightly different result is obtained with the various nutrients. Taking protein first it is seen that the total production of protein in human foods was, in the whole seven years, 28.6 million metric tons. The net subtraction of this fundamental nutrient, in the form of human food, amounted in the same period to 3.0 million metric tons. The net loss by export thus was about 10.5 per cent. of the production.

In the case of fat the net exports over the whole seven year period are almost exactly 10 per cent. of the production. The carbohydrate situation is that if the period from July, 1911 to July, 1918 is taken as a unit, there was no loss by export, but the people of the country had all the carbohydrate they produced, which was in round figures 115 million metric tons in the form of human foods, *plus* 28,943 metric tons imported. It is, of course, the fact that this is a sugar-importing nation which brings about this quite unexpected result.

Taking energy content as indicative of general food value it is seen that the net loss in seven years from this country by exports of human food was 49.6 million million calories, while the production in the same period was 963.6 million millions. The net loss thus amounted to about 5 per cent. of the production.

CHAPTER IX

THE CONSUMPTION OF HUMAN FOOD IN THE UNITED STATES

We come now to the first goal to which the long and tedious calculations in the preceding chapters have been leading, namely the consumption of human foodstuffs in the United States. Hitherto there have been available only the roughest guesses as to the total domestic consumption of all but a few items of food, such as wheat and sugar. If anyone were confronted, as the Food Administration was almost daily from the time it started, with the naive and simple question, "How much corn, or oats, or molasses, or fish, or milk, or nuts"—or any one of a long series of other foods—"is consumed annually in the United States as human food?" no accurate answer could be given. Yet the question is obviously a fair one, and one which somebody in the nation ought to be able to answer with a considerable degree of accuracy. For some 20 odd great staple commodities or groups of like commodities it is now possible to present figures of a relatively high degree of accuracy as to consumption. On the basis of these figures it is possible to discuss effectively many interesting and important problems; such as, for example, that of the relative significance of great groups of staples, like the grains and the vegetables, in the nutrition of the people of the nation. We can calculate with accuracy the total national food bill, and so forth.

The statistical material in this book has been so developed to this point that in order to get the consumption figures it is only necessary to add or subtract, according to the sign, the figures of Table 58 in the last chapter from those of Tables 7 and 11 of Chap-

ters III and IV. These two tables, 7 and 11, it will be recalled, give the net production of human foods. Of course it is necessary to group and combine certain items of Tables 7 and 11 to conform to the rubrics of Table 58, but this is easily done.

The final net results as to consumption of human foods are set forth in Table 61. In that table the results are given for the several nutrient values, protein, fat, carbohydrate and calories, only. This is the most scientific, and as soon as one becomes accustomed to it, by far the most useful way of thinking about food consumption.

There are certain points regarding the makeup of Table 61 which need to be mentioned here. It will be recalled that in an earlier chapter it was stated (p. 32) that no account was taken of "carry-over" or crop-end reserves. This policy has been followed throughout, and for the reasons earlier stated is undoubtedly the most accurate method possible to follow. For practically all *human foods* either one or both of the following conditions obtain regarding carry-overs: Either there is absolutely no definite information in existence regarding the amount of such carry-over, or it is certain that the amount is negligibly small in comparison with the total consumption. The one outstanding exception is wheat and its products. There the annual reserve on July 1 is accurately known and the amount is often large enough to be significant. Consequently it has seemed advisable in the final consumption table to make allowance for the carry-over of this crop each year. The theory of the thing is clear. As shown in Table 60 the total reserves of wheat and flour in the country on July 1, 1911, were the equivalent of 97,995,000 bushels of wheat. On July 1, 1912, the reserves were 84,189,000 bushels of wheat. The reserves being *smaller* at the end of 1911-12 than at the beginning means that the difference was consumed in this country. Or, for the year 1911-12, there should be added to the consumption figures arrived at by subtracting *net* exports from production, $97,995,000 - 84,189,000 = 13,806,000$ bushels. The same method has been followed for each year, except of course that when the reserves are larger at the end of the year than at the beginning the difference is subtracted from rather than added to the gross consumption.

The crop-end reserves of wheat and flour are shown in Table 60 for each year since 1900.

TABLE 60.—CROP-END RESERVES OF WHEAT AND FLOUR
(In Bushels)

On July 1 of year named	Total reserves	Farm reserves	Visible supply	Visible supply of flour as wheat	Wheat in other positions, esti- mated as 40 per cent. of visible wheat
1901	107,556,000	30,552,000	49,028,000	8,365,000	19,611,000
1902	110,125,000	52,437,000	35,783,000	7,592,000	14,313,000
1903	86,455,000	42,540,000	26,524,000	6,781,000	10,610,000
1904	81,055,000	36,634,000	26,329,000	7,560,000	10,532,000
1905	63,538,000	24,257,000	23,150,000	6,871,000	9,260,000
1906	108,340,000	46,053,000	39,776,000	6,601,000	15,910,000
1907	146,753,000	54,853,000	60,883,000	6,664,000	24,353,000
1908	72,425,000	33,797,000	23,256,000	6,070,000	9,302,000
1909	46,141,000	15,062,000	18,099,000	5,740,000	7,240,000
1910	79,814,000	35,680,000	25,417,000	8,550,000	10,167,000
1911	97,995,000	34,071,000	40,093,000	7,794,000	16,037,000
1912	84,189,000	23,876,000	36,999,000	8,514,000	14,800,000
1913	107,812,000	35,515,000	45,424,000	8,703,000	18,170,000
1914	81,006,000	32,236,000	28,646,000	8,666,000	11,458,000
1915	57,634,000	28,972,000	15,208,000	7,371,000	6,083,000
1916	179,174,000	74,731,000	66,560,000	11,259,000	26,624,000
1917	50,969,000	15,617,000	19,123,000	8,586,000	7,649,000
1918	17,504,000	8,283,000	3,713,000	4,023,000	1,485,000

One further point regarding wheat is to be noted. Since Chapter III was written a revision of the estimate of the 1917-18 wheat crop has been made. The final official estimate by the Food Administration¹ of that year's crop is 608,287,000 bushels, instead of the 620,000,000 bushels used in Chapter III. We have accordingly made this reduction in wheat figures for 1917-18 in Table 61.

¹ Cf. Official Statement of the U. S. Food Administration, Vol. I, No. 3, p. 14, August, 1918.

Average, 1911-12 to 1916-17.....	3,654,571	46	54	5,115,279	17	83	16,413,088	95	5	129,931,315	61	39

The first thing which impresses one about the consumption figures is their extreme uniformity from year to year, as compared with production, exports, imports, with which we have hitherto dealt. This is exactly what would be expected, of course. No matter how much production, exports and imports may fluctuate, within rather wide limits, the people of this country eat about the same amount

FIG. 30.—Showing the course of human food consumption in the United States from 1911 to 1918. Absolute figures in metric tons. Dash line denotes protein content of human food consumed; dot line denotes fat content; and dot-dash line denotes carbohydrate content.

each year. To have the statistical calculation come out to this result so beautifully is strong evidence of the correctness of the long and tedious preliminary calculations which have been presented in the earlier chapters. There has been a rather steady small increase in total gross food consumption, but as Fig. 31 so plainly shows, this has been very closely proportional to the increase in the population.

In the seven year period here discussed the greatest relative advance in consumption was in respect of fat, and the least relative advance in respect of protein. Carbohydrate content and calories increased in the seven years in amount consumed to a degree intermediate between fat and protein. The protein relative line falls below the population relative line each year after 1913-14. This

FIG. 31.—Relative curves for human food consumption. The figure for the year 1911-12 is taken as 100 in each case and the relative figure for each year calculated to that base. The population curve is included for comparison. Solid line denotes calories; dash line, protein; dot line, fat; dot-dash line, carbohydrate; circle line, population.

means that since 1913-14 somewhat less protein has been consumed in gross in proportion to the population. The relative line for fat was below the population line till 1914-15, and thereafter followed it closely.

The relative figures from which Fig. 31 is plotted are given in Table 63.

With such gratifying assurance of the smoothness of the consumption results we may proceed to an analytical discussion of the numerous highly interesting problems which center about human food consumption, and for which data have hitherto been lacking.

TABLE 63.—CONSUMPTION OF HUMAN FOODS, PRIMARY AND SECONDARY, RELATIVE TO 1911-12, TAKEN AS 100

Years	Population	Protein	Fat	Carbohy- drate	Calories (millions)
1911-12	100.0	100.0	100.0	100.0	100.0
1912-13	101.7	100.2	99.0	103.4	101.4
1913-14	103.4	104.3	100.3	110.7	106.1
1914-15	105.1	101.3	107.3	104.0	104.9
1915-16	106.8	106.3	105.3	109.6	107.6
1916-17	108.5	104.5	109.1	105.5	106.7
1917-18	110.2	106.4	110.9	110.2	110.0
Average, whole period	105.1	103.3	104.6	106.2	105.2
Average, 1911-12 to 1916-17	104.3	102.8	103.5	105.5	104.5

The first of such problems to which attention may be turned is: To what relative degree do primary, as distinguished from secondary, human foods contribute to the total nutritional intake of our population? From Table 62 it is seen that 47 per cent. of the protein consumed comes from primary sources and 53 per cent. from secondary sources. Thus, broadly speaking, the American people get over one-half of their protein from animal sources, exclusive of fish, which are included in the primary foods. This fact indicates at once the importance of maintaining the nation's animal herds intact and keeping the price of animal products at not too high a level, unless we are prepared to face the alternative of a radical and fundamental alteration in the established dietary habits of the people.

In general there has been but little change in this protein-source dietary habit in the seven years included in this study. What change there has been is in the direction of a smaller proportion of protein from secondary sources and a larger from primary, but the movement has been but slight. As would be expected, a much larger proportion of the total fat consumed in human food comes from secondary sources than is the case with protein. The figures are 82 per cent. from secondary sources and 18 per cent. from primary. Again there has been little change in the seven years. In spite of all propaganda from dietary cranks and from commercial interests it is clear that the American people depend to an overwhelming degree upon animal sources for their fat intake, rather

than upon vegetable oils, nuts and the like. This condition is naturally reversed as regards carbohydrate. Ninety-four per cent. of this nutrient comes from primary sources and only 5 from secondary. In the total nutritional calory intake 61 per cent. comes from primary foods and 39 per cent. from secondary.

FIG. 32.—Diagram showing the percentages of the total nutritional intake of the American people derived from primary and secondary sources.

It is interesting to compare the percentage of American nutritional intake derived from primary and secondary sources with corresponding British figures. Calculating roughly from Table I of the official British report¹ on the subject I find that 42 per cent. of the protein intake, 92 per cent. of the fat intake, and 35 per cent. of the energy value of the total nourishment of the population of

¹ The Food Supply of the United Kingdom. A report drawn up by a Committee of the Royal Society at the request of the Board of Trade. London (Cd. 8421), 1917, p. 35.

the United Kingdom comes from *secondary* sources. In other words, the British get less of their protein and calories and more of their fat from animal products exclusive of fish than the Americans do. The differences, however, are not great, indicating generally similar dietary habits in the two populations, a fact which is known on general grounds to be true.

FIG. 33.—Diagram showing the relative proportions of the American and the British food intake derived from animal sources (exclusive of fish).

The above comparisons regarding primary and secondary sources of human food are shown graphically in Figs. 32 and 33.

The next problem concerns the relative proportion of the total nutritional intake furnished by the several different large food commodity classes. The data on this point for the main groups are collected in Tables 64 to 67 inclusive. The arrangement of these tables is to give first the annual average for the six years preceding the entrance of the United States into the war, and then to give

1917-18, our first year in the war, separately. The reason for such a time division is obvious. There is no reason to suppose that the consumption of food in this country was affected by the war till the time we entered and the United States Food Administration began its work. Before then the population had gone on consuming food at about the usual normal rate. There was no reason or incentive to do otherwise, except in so far as price had an influence. But in 1917-18 a wholly new and extraordinary influence was brought into play to alter the national food habits. This was the Food Administration, which through its recommendations, on the one hand, and regulations on the other hand, sought to modify the consumption rate of certain commodities and succeeded in doing so, as will presently appear in detail.

In Tables 64 to 67 the percentage figures are first given separately and then accumulated to 100 in another column.

The data of Tables 64 to 67 are shown graphically in Fig. 34.

From these tables and diagrams it is seen that the grains stand at the head of the list in contribution of protein, carbohydrate and calories. Meats come first in contribution of fat, second in protein and calories. Thirty-six per cent. of our protein intake normally is in the form of grain, 26 per cent. in meats and 20 per cent. in dairy products. These three great commodity groups together make up nearly 83 per cent. of the total protein intake.

The total consumption of human food was absolutely higher in 1917-18 than the average of the preceding six years. This is to be expected from the increase of the population, and means nothing till converted to relative terms. But the proportion of the total contributed by the grains and meats is smaller in 1917-18. In other words, the two great commodity groups on which the most stress was laid in the conservation campaign of the Food Administration show an absolute reduction in the part which they play in nutrition. The effect of the conservation work will, however, be more clearly shown when we come to the consideration of individual commodities.

Of the fat normally consumed 51 per cent. is furnished by the meats as a group; 27 per cent. by the dairy products; and 12 per cent. by the vegetable oils and nuts. The grains normally furnish 3.98 per cent. of the fat intake and in 1917-18 this rose slightly to 4.16, due to the increased consumption of cornmeal.

TABLE 64.—CONSUMPTION OF PROTEIN IN HUMAN FOODS, PRIMARY AND SECONDARY, IN THE UNITED STATES, ARRANGED BY GROUPS IN ORDER OF MAGNITUDE

The sugars stand second in the list as contributors of carbohydrate to consumption, with 26 per cent. of the total, to which 56 per cent. is furnished by the grains. Of the remainder of the carbohydrate intake vegetables normally contribute about 9 per cent., the dairy products 5 per cent. and the fruit 4 per cent.

FIG. 34.—Showing the percentage contribution of the different great food commodity groups to the nutritional intake of the United States, for (a) six years before our entry into the war and (b) 1917-1918.

The energy values of the groups are especially interesting as furnishing a general index of food values. Of the total energy furnished by the human food consumed 35 per cent. comes from the grains, 22 per cent. from the meats, 15 per cent. from the dairy products and 13 per cent. from the sugars. These four groups make up about 85 per cent. of the total energy value of all the food consumed. Vegetables contribute only about 5 per cent. fruit and poultry about 2 per cent. each, and vegetable oils and nuts nearly 5 per cent.

On the basis of Table 67 it is of interest to examine somewhat more carefully the changes in consumption rate in 1917-18 as compared with the average of the six preceding years. Such a comparison is made in Table 68 and shown graphically in Fig. 35.

TABLE 68.—SHOWING THE CHANGES IN FOOD CONSUMPTION IN THE UNITED STATES IN 1917-18 AS COMPARED WITH THE AVERAGE ANNUAL CONSUMPTION IN THE SIX PRECEDING YEARS
(Millions of Calories)

Population.....	5,662,979	5.73

FIG. 35.—Diagram showing the increase or decrease in food consumption in 1917-18 as compared with the average of the preceding six years.

From Table 68 and the diagram it is observed that the total increase in human food consumption in 1917-18 was less (nearly $\frac{1}{2}$ per cent.) proportionately than the increase in population, both being compared with the average of the six preceding years. The consumption of meats practically did not increase at all, and the consumption of grains only about 1 per cent.

The great increases were first in the consumption of vegetables and oils and nuts, amounting to 30 per cent. in the one case and 29 per cent. in the other, and second in oleomargarine where the consumption increased nearly 116 per cent. in 1917-18 over the average of the preceding six years. In the case of vegetables and oils and nuts the increased consumption in 1917-18 is probably to be attributed largely to the activity of the Food Administration in urging the consumption of these commodities to afford a relief of the pressure on wheat and meat products. In the case of oleomargarine the increased consumption is clearly due entirely to a favorable price differential as compared with butter and lard, taking into account palatability.

The only two great commodity groups showing decreases in consumption in 1917-18 are fruits and fish. In both cases the result is probably to be explained by price influences, taken together with palatability and popular ideas as to relative necessity in the diet. For example the price of meat may rise relatively much more than that of fruits or fish without leading to any reduction in consumption, owing to the general belief that meat is a more necessary article of diet than the other two sorts of food mentioned.

We may next consider the gross consumption of individual commodities on the same plan that has just been used in handling the groups. The data are given in Tables 69 to 72, inclusive. In these tables it will be noted that the cumulated percentage columns run to more than 100 per cent. by trifling amounts. This is to take care of the item "other meat products" which appears in the net export table but not in production. In the main consumption table it is carried into the sub-total "Meats" but does not appear as a separate item, because of the impossibility of calculating it as such.

The data of Tables 69 to 72 inclusive are shown, exhibited graphically in Figs. 36 to 39.

Taking first the protein consumption, as given in Table 69, it is seen that wheat stands at the head of the list as a source of protein for the population of this country, contributing nearly 29 per cent. normally to the total. Dairy products are second with 20 per cent. of the total. Beef with 14 per cent. and pork with 11 per cent.

FIG. 36.—Diagram showing the percentage of the total protein consumed in the United States contributed by each of 23 commodities. The solid bars denote the average consumption in the six years preceding our entry into the war. The cross hatched bars denote the consumption in 1917 and 1918.

stand next. The other commodities contributing more than 2 per cent. to the total protein intake of the population are, in the order named: Poultry and eggs, corn, potatoes and fish. Taken together, these 8 commodities furnish 92 per cent. of the total protein intake. We see here again, just as in the case of the production tables, that a very few commodities furnish a very large

percentage of the nutritional intake. This fact, in and of itself, helps enormously toward the possibility of making an investigation such as this substantially accurate in its results. It is clear that the minor items omitted from the calculations have no significance in the final general result. If four food commodities furnish nearly 75 per cent. of the total protein ingested it is obvious that a large error, or even the entire omission, of single ones of the other minor items can have but little effect.

FIG. 37.—Diagram showing the percentage of the total fat consumed in the United States contributed by each of 23 commodities. The solid bars denote the average consumption in the six years preceding our entry into the war. The cross hatched bars denote the consumption in 1917 and 1918.

Comparing the order of the commodities in 1917-18 with the average of the six preceding years, it is seen that the only change of position among the eight commodities normally furnishing over 90 per cent. of the protein is in respect of the last one on the list, namely, fish. In 1917-18, the legumes (beans and peas) moved up to the eighth place and fish moved to the ninth place.

Turning to the fat consumption, it is seen that approximately 40 per cent. of the total fat in the nutritional intake of this country

comes from pork and its products. The hog is in a class by itself as a source of fat for human nutrition, with the population of this country. Dairy products stand second in the list, with approximately $27\frac{1}{2}$ per cent. of the total. After the dairy products there is a considerable drop in percentage contribution in passing to the next item on the list, namely the vegetable oils, which normally furnish only about 10 per cent. of the fat intake. Beef contributes

FIG. 38.—Diagram showing the percentage of the total carbohydrate consumed in the United States contributed by each of 23 commodities. The solid bars denote the average consumption in the six years preceding our entry into the war. The cross hatched bars denote the consumption in 1917 and 1918.

almost exactly the same percentage. The four commodities named together furnish nearly 87 per cent. of the total fat intake. Only one other commodity group—namely, poultry and eggs—furnishes more than 2 per cent. normally.

In 1917-18 there are some changes of significance in the relative position of the commodities as fat contributors. The first four items, pork, dairy products, oils and beef, stand in the same order in 1917-18 as in the six years preceding. Nuts moved up in 1917-18 to the

fifth place, from the seventh, which they had occupied before. Oleomargarine moved from the tenth place to the seventh. Corn, in spite of the increased consumption in 1917, dropped from the sixth place to the eighth in percentage contribution. Twelve of

FIG. 39.—Diagram showing the percentage of the total energy value of the food consumed in the United States contributed by each of 23 commodities. The solid bars denote the average consumption in the six years preceding our entry into the war. The cross hatched bars denote the consumption in 1917 and 1918.

the great commodity groups before our entry into the war, and 13 in 1917-18, contribute less than 1 per cent. to the total fat intake.

In carbohydrate consumption wheat stands at the head of the list with over 42 per cent. normally. The sugars stand second with about 26 per cent., and corn with 11 comes next. These three commodities, together with potatoes and the dairy products, con-

tribute altogether 90 per cent. of the carbohydrate intake. There is no change in the relative position of the commodities falling in the 90 per cent. group in 1917-18 as compared with the average of the six preceding years.

A noteworthy feature of this Table 71, dealing with carbohydrates is the relative position of the sugars. Many persons regard sugar as a pleasant but not essential part of the dietary. It is obvious enough that this is a mistaken point of view. Any commodity which furnishes nearly 26 per cent. of the carbohydrate intake of the population may be regarded as an important essential. To get an idea of the importance of the sugar relatively it is only necessary to compare it with some of the items farther down in the table. For example, we see that the sugars contribute more than 20 times as much to the carbohydrate intake of the nation as does rice.

In Table 72 we get a summarized view of the general nutritional importance of the several food commodities, because here we are dealing with the energy content as measured in calories. The order of the products in this table may be taken as the general order of nutritional significance of the great staple foods in this country. Wheat stands at the head of the list, contributing nearly 26 per cent. to the total. Pork comes next with normally 16 per cent., and dairy products third with 15 per cent., and the sugars fourth with 7 per cent. Then follow corn, beef, the vegetable oils, potatoes, poultry and eggs. These 9 commodity groups together make up over 91 per cent. of the total nutritional intake of the population. The smallest contribution to the total nutrition is made by oranges furnishing about $\frac{1}{10}$ of 1 per cent. of the total. Bananas and fish furnish only about $\frac{4}{10}$ of 1 per cent. of the total, and rye and rice only a little more.

The changes in 1917-18 as compared with the average in the six preceding years, as shown in Table 72, are extremely interesting. The figures show in much more detail than any that have been available hitherto the precise effects of the conservation and substitution campaign of the United States Food Administration during 1917-18. While wheat normally contributes 25.9 per cent. of the total nutritional intake (as measured by energy value), in 1917-18 it contributed but 21.9 per cent. Or, put in another way this result means that as a result of the conservation campaign, wheat fell off $\frac{1}{6}$ in its contribution to the natural nutrition. To go farther down

the table, rice which normally contributed but 0.6 of 1 per cent. to the total nutritional intake contributed 1 per cent. in 1917-18. Rice, in other words, gained by $\frac{2}{3}$ what it was before in its importance in feeding the American people.

The changes in consumption, as indicated in Table 72, are of such great interest that it is worth while to examine them more in detail. To this end a table on the same plan as Table 68 is shown.

TABLE 73.—SHOWING THE CHANGES IN FOOD CONSUMPTION IN THE UNITED STATES IN 1917-18 AS COMPARED WITH THE AVERAGE ANNUAL CONSUMPTION OF SIX PRECEDING YEARS FOR 23 STAPLE HUMAN FOODS
(Millions of Calories)

Commodity	Increase of consumption in 1917-18 over 6 year average	Decrease of consumption in 1917-18 under 6 year average	Percentage increase	Percentage decrease

Oranges.....	45,281	32.61
Total net increase.....	6,888,424	5.30
Population.....	5,662,979	5.73

The data of Table 73 are exhibited graphically in Fig. 40. In this diagram the total length of the bars from the 0 line shows the total percentage increase or decrease in consumption in 1917-18 as compared with the preceding six years. The cross-hatched portion of each bar shows the percentage increase in population, and therefore the part of the increased consumption to be expected as a result of population increase. Where the black bar is below the

FIG. 40.—Showing the percentage increase or decrease in consumption in 1917-1918 as compared with the annual average of the six years preceding. For explanation see text.

top of the cross-hatched population bar it means a conservation. Thus the true conservation on wheat amounted to $10.80 + 5.73 = 16.53$ per cent. of the normal average consumption.

The table and diagram bring out very clearly the effectiveness of the Food Administration's campaign for conservation and substitution in foods. It will be noted at once that the commodities showing great increases in consumption in 1917-18 over the preceding years are, for the most part, those which the Food Adminis-

tration urged to be substituted for articles of which the supply was less abundant, and for which the needs of the Allies were greater. Thus, rye which constituted the most popular of the substitutes for wheat in the public mind, shows the greatest increased consumption in 1917-18. Next to it stands the "Other cereals" of our classification, including barley and buckwheat. Nuts, rice and the vegetables generally show increases beyond the population increase, showing that the people very generally followed the suggestions of the Food Administration to consume more of these products and save wheat. The articles on which the Food Administration most strongly urged conservation—namely, wheat, beef, mutton, pork and the sugars—all show either a consumption actually below the normal average, or else a very slight increase in consumption, well below the population percentage increase. In either case a real and substantial conservation is, of course, shown. The decrease in consumption of the most popular fruits, oranges, apples and bananas, is largely if not entirely explained by high prices for those products.

The most interesting stage of any discussion of food—namely, the per capita per diem consumption, may be considered next. Calculating the results on this basis puts them in a form where one may form a better judgment of their meaning and compare them with accepted dietary standards. In this connection it is to be remembered that hitherto there have been no careful studies on a per capita basis of the actual nutritional intake of the population as a whole. All dietary standards are based not on the actual practice of the whole population, but rather upon dietary studies made on restricted groups of selected individuals. While a very large number of such studies have been made by the United States Department of Agriculture, particularly from ten to twenty years ago, it must be obvious that since such studies are made on selected small groups they can only inferentially give any picture of what is taking place in the population as a whole. The theory of random sampling makes it clear that any considerable inference from dietary studies, as they have been carried on, to the whole population rests on an exceedingly dubious foundation. It will therefore be of great interest to compare the results of the present careful investigation of the population as a whole with the results of previous dietary studies.

In reducing consumption data to a per capita basis it would obviously be foolish to take the actual total population as a base,

for the reason that the amount of food consumed changes with the age of the individual, particularly in early life. On account of this fact the usual practice in computations of this kind is reduced, not to a per capita basis, but to an adult man basis. In doing this a fractional factor is used to multiply the number of individuals of certain lower ages, the magnitude of the factor being proportional to the relation which the nutritional intake of the individual at the younger age bears to that of an average adult man.

In the present study the following age-intake factors have been used:

Age in years	Man value factor
0-5.....	0.50
6-13.....	0.77
14-18, male.....	1.00
14-18, female.....	0.83
19 on, male.....	1.00
19 on, female.....	0.83

The man factor values here used have been adopted after careful study of the subject. They differ in detail somewhat from those adopted by English physiologists in similar calculations, but in the net end result come to much the same thing.

Applying these factors to the total population of the United States, and assuming that the age distribution of the population is the same in each of the years studied we get the population in terms of adult men as set forth in Table 74, for the midyear point of each of the years included in this study. The population equivalents in Table 74 are used for the base for the per capita per diem calculations which follow.

TABLE 74.—POPULATION OF CONTINENTAL UNITED STATES IN TERMS OF ADULT MEN

Year	Population equivalent in adult men, January 1
1912	79,571,000
1913	80,930,000
1914	82,289,000
1915	83,648,000
1916	85,007,000
1917	86,366,000
1918	87,724,000

Before entering on the detailed discussion of per capita consumption figures it is well to recall a point which is liable to escape attention, unless special attention is called to it. This is the fact that the final figures in this chapter, which are called "consumption figures," really include something more than consumption in a nutritional sense. They include the food actually eaten plus that which is wasted by loss in cooking, in garbage, etc. It is necessary to be entirely clear on this point. In calculating the nutrients in earlier chapters, use has been made of factors which allowed for *inedible* refuse, so that all of the inedible portions of the foods as produced or imported have already been deducted in the calculations up to this point. Even after all deductions of inedible portions have been made, however, it is obvious that there is still a considerable amount of loss and wastage of strictly edible material, which might be saved and consumed under a theoretically ideal system of preparing food for the table plus a conscientious ingestion of every bit of edible material. Of course, as a matter of fact, neither of these theoretically ideal conditions at all prevail. There is a considerable loss of nutrient values in the process of cooking as ordinarily practised. This loss is undoubtedly greater for fats than for any other of the nutrients. It is a troublesome and time-consuming process for the housewife to conserve and utilize all of the fat which gets melted and floats about in the water in which foods are cooked, or adheres to the utensils in which they are prepared. Nor, in the minds of most people, is there any necessity or desirability of saving this fat. In fact, a great many people in this country object very strongly to what they designate as "greasy cooking." Consequently, floating fat of soup stock is skimmed off and thrown away in the vast majority of instances. The result is that in calculations made in the way those of this study have been made, which include the total nutrient value in the edible portion of food materials, after deducting inedible waste and deducting the losses which accrue up to the time the food reaches the consumer, there is bound to be an apparently high consumption of fats. The figures here presented are really statements of consumption plus edible waste and should be so regarded.

Another important factor is that of edible waste in garbage: That is to say, the uneaten portion of the prepared food which is edible and might be consumed, but is not for reasons of taste, over-estimation of ingestive capacity, etc.

It is quite impossible to arrive at any accurate estimate of what the amount of losses of nutrients in cooking and in avoidable wastage of edible material is. On the first point it would be extremely difficult ever to gather accurate data because the practice of housewives and cooks varies so enormously in this regard. That a great deal can be accomplished in reducing the amount of edible material going into the garbage can has been demonstrated with both the civilian and the Army population of the United States during the past year.¹

The recent study of Murlin (*loc. cit.*) gives the data regarding edible waste obtained from the nutritional surveys of the training camps. The average figures for 213 messes show that 7 per cent. of the protein supplied was wasted, 9 per cent. of the fat and 6 per cent. of the carbohydrate. Because of special conditions surrounding the investigation, however, and because of the differences of camp life, these figures are not at all applicable to civilian conditions.

Looking at the matter from the national point of view, it seems probable that of the protein in human foods left in the country for consumption in the statistical sense, it is safe to say that 5 per

TABLE 75.—SUMMARY OF CONSUMPTION PER ADULT MAN

¹ Pearl, R., Statistics of Garbage Collection and Garbage Grease Recovery in American Cities, Jour. Ind. Eng. Chem., Vol. 10, No. 11, p. 927, 1918, and Murlin, J. R., Diet of the U. S. Army Soldier in the Training Camp, Jour. Amer. Med. Assoc., Vol. 71, pp. 950-951, 1918.

cent. is lost in edible wastage; of the fat left in the country for consumption as human food, it is believed that at least 25 per cent. is lost through wastage. This figure seems large, but it probably underestimates rather than overestimates the fact. Of the carbohydrates, probably there is 20 per cent. of edible wastage.

The total statistical consumption (ingestion plus edible wastage) of human food in the United States, by years from 1911 to 1918 is shown on an "adult man" per capita basis in Table 75.

Applying the estimated percentage deductions for edible wastage stated above to the per capita average for the whole period we have the following results for ingested human food:

114 grams protein	per man	per day
127 grams fat	per man	per day
433 grams carbohydrate	per man	per day
3424 calories	per man	per day

These figures are probably very close to the fact as regards protein and carbohydrate. They are probably somewhat too high still as regards fat, because the edible wastage of this component is higher than the 25 per cent. used. The intention, however, has been to use the most conservative figures in estimating waste.

For purposes of comparison Table 76 is inserted. This table is based upon certain American dietary studies analyzed in the writer's statistical laboratory.

TABLE 76.—SUMMARY OF SOME DIETARY STUDIES IN 11 GROUPS OF 116 FAMILIES

	No. of families	Average yearly income	Days per man	Per man per day			
				Protein, grams	Fat grams	Carbohydrates grams	Energy, calories

Average.....	116	1771*	260	95	113	447	3185

*Average of 104 families (farmers excluded).

The general agreement of these results with those set forth in the present study, which were reached by totally different procedure, is evident. The statistical estimate of per capita protein consumption over the whole population is distinctly higher than in this small group. The fat consumption is higher but not by so large an amount as protein. The farmers and professional men show

FIG. 41.—Diagram showing the course of gross consumption of protein, fat and carbohydrate in human food from 1911-12 to 1917-18, per adult man per diem. Dash line denotes protein; dot line, fat; dash-dot line, carbohydrate.

a higher net energy intake than the general average for the whole country, which would, of course, be expected. Mechanics are a little lower than the average for the country in energy intake.

In any case there is one fact which must not be lost sight of, namely that while the figures of Table 75 do in fact represent ingestion and waste it still is true, and the constancy of the figures in successive years proves its truth, that to maintain naturally and unconsciously a contented feeling the population in respect of

nutrition, actually uses up the amounts of nutrients indicated in Table 75. To make these gross consumption figures materially less would require a profound readjustment of the dietary and culinary habits of the people, fixed by centuries of usage. Discussion of the minimum protein, fat and carbohydrate requirements of a nation are in considerable degree academic if they base themselves upon net

FIG. 42.—Diagram showing the energy value in calories of the gross consumption of human food, per adult man per day.

consumption rather than gross consumption. A considerable excess over any agreed upon minimum *physiological* requirements must always be allowed, because there will inevitably be, in fact, a margin between actual gross consumption and net physiological ingestion or utilization. The present study, through the figures summarized in Table 75, gives a clearer and probably more nearly exact picture of what this margin between net and gross consumption must be, in a population of the habits of the American

people, than has hitherto been available. It may well be theoretically true that a man needs only 75 grams or 50 grams of protein per day to sustain life and health, but in actual fact the American man uses up, in one way or another, about 120 grams a day. Furthermore, if the last seven years experience is any criterion, he will continue to use up about 120 grams per diem until such time as his general habits of life are in some manner rather profoundly changed. Doubtless they can be changed. But until they are, one must count on supplying about 120 grams of protein per day to each man equivalent component of the population.

The data of Table 75 are shown graphically in Figs. 41 and 42.

From these diagrams it is apparent that there has been only a very slight decrease in per capita gross food consumption since 1911. This probably does not mean that the population is eating any less, but that because of the gradually rising prices through all this period there has been a minutely slight narrowing of the margin between gross and net consumption, or, put in another way, there has been some reduction in the wastage of edible foods.

In Table 77 are shown the gross consumption figures, on a per capita per day adult man basis, for all commodities.

In bringing this book to a conclusion, the writer would emphasize that he has been solely concerned in the presentation of an accurate picture of the *facts* regarding an obviously important matter, national nutrition. He has no theories to propound about these facts, and discussions about the relations of national nutrition to various social, political, medical, economic, or industrial problems are conspicuously absent from the book. This is deliberate. It does not indicate that the writer fails to perceive these problems, and their relation to national nutrition. It means rather that he has thought it wiser to separate sharply the facts as such from their possible application. The book constitutes a definite piece of statistical research, precisely delimited as to scope. It makes available for the first time a knowledge, to at least the first degree of approximation, of how much and what kinds of food the American people as a great whole eat.

APPENDIX

THE CONSUMPTION OF NUTRIENTS BY DOMESTIC ANIMALS IN THE FORM OF FEEDS AND FODDERS

It was the original intention in this study to follow the statistical analysis of human food consumption with an equally detailed and searching analysis of the consumption of nutrients by the domestic animals. Indeed, the preliminary statistical work had been completed. But the signing of the armistice and the consequently necessary diversion of the writer's energies and interests into totally different channels have made the carrying out of the original plan impossible. It does, however, appear desirable that all of the work done on the animal feeds and fodders should not be lost. Consequently, I am inserting here as an appendix the final table of *consumption* of animal feeds in the several years. The figures in this table were reached by precisely the same statistical plan as has been followed in the case of human foods in the body of the book. Exports and imports were balanced to get net exports. These net exports were deducted from net production (after taking out losses, etc.) to find net consumption. In the final table here reproduced many single products, which in the intermediate calculations were kept separate, are grouped in large general classes, such as "Wheat and products." This rubric includes all the wheat milling by-products, wheat fed as such, etc.

Beyond the figures given in this table should come the nutrients derived by grazing animals from green pasturage harvested by the animals themselves. In certain of the European countries attempts have been made to estimate this exceedingly difficult quantity. Under the conditions of animal husbandry prevailing in the United States, and having due regard to the enormous size of the country and the consequent diversity of conditions, it seems to the writer hopelessly impossible to arrive at a significant national estimate of the amount of nutriment got by animals from pasturage. One can, of course, guess at a figure, but there is no means of evaluating the probable error of the guess. Consequently, the figures given in the following table are to be interpreted as minimum amounts of nutrients consumed by domestic animals, which can be definitely accounted for statistically. To them should be added the unknown *X* of pasturage.

SHOWING THE CONSUMPTION OF ANIMAL FEEDS AND FODDERS
